THE CONVEX AND CONCAVE DECOMPOSITION OF MANIFOLDS WITH REAL PROJECTIVE STRUCTURES

Suhyoung Choi

Abstract. — We try to understand the geometric properties of $n$-manifolds ($n \geq 2$) with geometric structures modeled on $(\mathbb{R}P^n, \text{PGL}(n+1, \mathbb{R}))$, i.e., $n$-manifolds with projectively flat torsion free affine connections. We define the notion of $i$-convexity of such manifolds due to Carrière for integers $i, 1 \leq i \leq n-1$, which are generalization of convexity. Given a real projective $n$-manifold $M$, we show that the failure of an $(n-1)$-convexity of $M$ implies an existence of a certain geometric object, $n$-crescent, in the completion $\hat{M}$ of the universal cover $\tilde{M}$ of $M$. We show that this further implies the existence of a particular type of affine submanifold in $M$ and give a natural decomposition of $M$ into simpler real projective manifolds, some of which are $(n-1)$-convex and others are affine, more specifically concave affine. We feel that it is useful to have such decomposition particularly in dimension three. Our result will later aid us to study the geometric and topological properties of radiant affine 3-manifolds leading to their classification. We get a consequence for affine Lie groups.

Résumé (La Décomposition convexes et concaves de variétés avec les structures projectives réelle). — Nous essayons de comprendre les propriétés géométriques de $n$-variétés ($n \geq 2$) avec les structures géométriques modelées sur $(\mathbb{R}P^n, \text{PGL}(n+1, \mathbb{R}))$, i.e., les variétés de dimension $n$ avec les connexions affines dont la courbure et la torsion sont nulles. Nous définissons la notion de $i$-convexité de telles variétés due à Carrière pour les entiers $i, 1 \leq i \leq n-1$, qui sont la généralisation de convexité. Étant donné une $n$-variété projective réelle $M$, nous essayons de montrer le fait que l'échec d'une $(n-1)$-convexité de $M$ implique une existence d'un certain objet géométrique, $n$-croissant, dans le complétant $\hat{M}$ du revêtement universel $\tilde{M}$ de $M$. Nous prouvons aussi que cela implique encore l'existence d'un type particulier de sous-variété dans $M$ et donne une décomposition naturelle de $M$ en variétés projectives réelles plus simples, quelques-unes d'entre elles sont $(n-1)$-convexes et les autres sont affines, plus précisément affines concaves. Nous jugeons qu'il est utile d'avoir une telle décomposition, en particulier à trois dimensions. Notre résultat aidera plus tard à étudier les propriétés géométriques et topologiques de 3-variétés affines radiales qui mène à leur classification. Nous obtenons une conséquence pour les groupes Lie affines.

PREFACE

The purpose of this monograph is to give a self-contained exposition on recent results in flat real projective structures on manifolds. The main result is that manifolds with such structures have canonical geometric decomposition to manifolds with more structures, i.e., ones with better convexity properties and ones which have affine structures of special types.

We hope that this book exposes some of the newly found materials in real projective structures so that more people might become interested in this topic. For that purpose, we include many details missing from previous papers and try to show that the techniques of this paper are at an elementary level requiring only some visualization in spherical and real projective geometry.

Presently, the global study of real projective structures on manifolds is a field which needs to mature with various relevant tools to be discovered. The fact that such geometric structures do not have metrics and such manifolds are often incomplete creates much confusion. Also, as these structures are often assembled in extremely complicated manner as can be seen from their complicated global charts, or developing maps, the manifolds with such structures cannot be seen as having covers in subsets of model geometric spaces. This means that the arguments must be somewhat delicate.

Let us state some reasons why we are interested in real projective structures: Firstly, our decomposition will be helpful for the study of 3-manifolds with flat real projective structures. Already, the theory helps us in classification of radiant affine 3-manifolds (see [14]).

All eight of homogeneous 3-dimensional Riemannian geometries can be seen as manifestations of projective geometries, as observed by Thurston. More precisely, Euclidean, spherical, and hyperbolic geometries have projective models. The same can be said of $\text{Sol}$-, $\text{Nil}$-, and $\text{SL}(2, R)$-geometries. $H^2 \times S^1$- and $S^2 \times S^1$-geometries are modeled on $\mathbb{R}P^2 \times \mathbb{R}P^1$. Hence, every 3-manifold with homogeneous Riemannian structure has a natural real projective structure or a product real projective structure. One could conjecture that many 3-manifolds admit real projective structures although we do not even have a clue how to go about studying such a question.
Classical affine and projective geometries have plethora of beautiful results giving much insight into Euclidean, spherical, and hyperbolic geometries. We expect that such classical theorems will have important roles to play in the global study of projective structures on manifolds although in the present paper only very small portion of classical geometry is ever used.

As we collect more results on various geometric structures on manifolds, we may gain more perspectives on topology of manifolds which are not available from studying relatively better understood Riemannian homogenous geometric structures. By examining more flexible geometric structures such as foliation, symplectic, contact, conformal, affine, or real projective structures, we may gain more informations about the nature of geometric structures and manifolds in general. (We note here that the comparative study of the geometric structures still have not been delved into much.)

The author thanks Bill Thurston who initiated me into this subject which has much beauty, Bill Goldman who had pioneered some early successful results in this field, Yves Carrière who posed many interesting questions with respect to affine structures, and Hyuk Kim for many sharp observations which helped me to think more clearly. The author benefited greatly from conversations with Thierry Barbot, who suggested the words “convex and concave decomposition”, Yves Benoist, Richard Bishop, Craig Hodgson, Michael Kapovich, Steven Kerckhoff, Sadayshi Kojima, François Labourie, Kyung Bai Lee, John Millson, and Frank Raymond. The author thanks the Global Analysis Research Center for generous support and allowing me to enjoy doing mathematics at my slow and inefficient pace.

The author thanks the referee for suggesting a number of improvements on his writing and am grateful to Mrs. Kyunghee Kim and the editors for translating the abstract in French.

PART I

AN INTRODUCTION TO REAL PROJECTIVE STRUCTURES
CHAPTER 1
INTRODUCTION

From Ehresmann’s definition of geometric structures on manifolds, a real projective structure on a manifold is given by a maximal atlas of charts to $\mathbb{R}P^n$ with transition functions extending to projective transformations. (For convenience, we will assume that the dimension $n$ of manifolds is greater than or equal to 2 throughout this paper unless stated otherwise.) This device lifts the real projective geometry locally and consistently on a manifold. In differential geometry, a real projective structure is defined as a projectively flat torsion-free connection. Another equivalent way to define a real projective structure on a manifold $M$ is to give an immersion $\text{dev} : \tilde{M} \to \mathbb{R}P^n$, a so-called a developing map, equivariant with respect to a so-called holonomy homomorphism $h : \pi_1(M) \to \text{PGL}(n+1, \mathbb{R})$ where $\pi_1(M)$ is the group of deck transformations of the universal cover $\tilde{M}$ of $M$ and $\text{PGL}(n+1, \mathbb{R})$ is the group of projective transformations of $\mathbb{R}P^n$. (The pair $(\text{dev}, h)$ is said to be the development pair.) Each of these descriptions of a real projective structure gives rise to a description of the other two kinds unique up to some natural equivalences.

The global geometric and topological properties of real projective manifolds are completely unknown, and are thought to be very complicated. The study of real projective structure is a fairly obscure area with only handful of global results, as it is a very young field with many open questions, however seemingly unsolvable by traditional methods. The complication comes from the fact that many compact real projective manifolds are not geodesically complete, and often the holonomy groups are far from being discrete lattices and thought to be far from being small such as solvable. There are some early indication that this field however offers many challenges for applying linear representations of discrete groups (which are not lattices), group cohomology, classical convex and projective geometry, affine and projective differential geometry, real algebraic geometry, and analysis. (Since we cannot hope to mention them here appropriately, we offer as a reference the Proceedings of Geometry and Topology Conference at Seoul National University in 1997 [18].) This area is also an area closely related to the study of affine structures, which are more extensively studied with regard to affine Lie groups.
Every Riemannian hyperbolic manifold admits a canonical real projective structure, via the Klein model of hyperbolic geometry with the hyperbolic space embedded as the interior of a standard ball in $\mathbb{R}P^n$ and the isometry group $\text{PSO}(1,n)$ as a subgroup of the group $\text{PGL}(n+1,\mathbb{R})$ of projective automorphisms of $\mathbb{R}P^n$ (see [22] and [10]).

They belong to the class of particularly understandable real projective manifolds which are convex ones. A typical convex real projective manifold is often a quotient of a convex domain in an affine patch of $\mathbb{R}P^n$, i.e., the complement of a codimension one subspace with the natural affine structure of a complete affine space $\mathbb{R}^n$, by a properly discontinuous and free action of a group of real projective transformations (see Theorem 4.5). It admits a Finsler metric, called Hilbert metric, which has many nice geometric properties of a negatively curved Riemannian manifold though the curvature may not be bounded in the sense of Alexandrov (see [24]).

An affine structure on a manifold is given by a maximal atlas of charts to an affine space with transition functions affine transformations. Affine manifolds naturally admit a canonical real projective structure since an affine space is canonically identified with the complement of codimension one subspace in the real projective space $\mathbb{R}P^n$ and affine automorphisms are projective. In particular, Euclidean manifolds are projective. Of course there are many affine manifolds which do not come from Euclidean manifolds and most affine structures on manifolds are expected to be not convex (see the classification of affine structures on tori by Nagano-Yagi [27]).

Not all real projective manifolds are convex (see [31] and [22]). However, in dimension two, we showed that closed real projective manifolds are built from convex surfaces. That is, a compact real projective surface of negative Euler characteristic with geodesic boundary or empty boundary decomposes along simple closed geodesics into convex surfaces (see [10], [11], and [13]). With Goldman’s classification of convex real projective structures on surfaces [22], we obtain a classification of all real projective structures on surfaces [17].

Also, recently, Benoist [5] classified all real projective structures, left-invariant or not, on nilmanifolds some of which are not convex. Again, the decomposition into parts admitting homogeneous structures was the central results. His student Dupont [19] classifies real projective structures on 3-manifolds equal to $\text{Sol}/\Gamma$ for where $\text{Sol}$ is a 3-dimensional solvable Lie group and $\Gamma$ is a cocompact discrete subgroup.

The real projective structures on 3-manifolds are unexplored area, which may give us some insights into the topology of 3-manifolds along with hyperbolic and contact structures on 3-manifolds.

Three-dimensional manifolds with one of eight Riemannian homogeneous geometric structures admit canonical real projective structures or product real projective structures, as observed by Thurston: Manifolds with hyperbolic, spherical, or Euclidean structures admit canonical real projective structures since hyperbolic, spherical, and Euclidean geometries can be realized as pairs of open subspaces of the real projective space and subgroups of projective automorphisms of the respective subspaces. Similarly, manifolds with $\text{Sol}$-, $\text{Nil}$-, and $\text{SL}(2,\mathbb{R})$-structures admit real projective
structures. manifolds with $H^2 \times \mathbb{R}$- and $S^2 \times \mathbb{R}$-structures have product real projective structures modeled on $\mathbb{R}P^2 \times \mathbb{R}P^1$. (See Theorem A.1 using results of Molnár [26].)

Also, given a hyperbolic Dehn surgery space of a hyperbolic knot complement in the 3-sphere, the boundary point is often realized by manifolds with degenerate geometric structures. An interesting question by Hodgson is how to understand the degeneration process by real projective structures perhaps by renormalizing the degeneration by projective maps (see the thesis by Suarez [30]).

We might ask whether (i) real projective 3-manifolds decompose into pieces which admit one of the above geometries or (ii) conversely pieces with such geometric structures can be glued into real projective 3-manifolds by perturbations. (These are questions by Thurston raised around 1982.)

Goldman (see [1, p. 336]) asked which irreducible (Haken) 3-manifolds admit real projective structure? A very exciting development will come from discovering ways to put real projective structures on 3-manifolds other than from homogeneous Riemannian structures perhaps starting from triangulations of 3-manifolds.

A related question asked by John Nash after his showing that all smooth manifolds admit real algebraic structure is when does a manifold admit a rational structure, i.e., an atlas of charts with transition functions which are real rational functions. Real projective manifolds are rational manifolds with more conditions on the transition functions.

These questions are at the moment very mysterious and there is no evidence that they can be answered at all. This paper initiates some methods to study the question (i). We will decompose real projective $n$-manifolds into concave affine real projective $n$-manifolds and $(n-1)$-convex real projective $n$-manifolds.

In three-dimensional case, our resulting decomposition into 2-convex 3-manifolds and concave affine 3-manifolds often seem to be along totally geodesic surfaces, which hopefully will be essential in 3-manifold topology terminology. Thus, our remaining task is to see if 2-convex real projective 3-manifolds admit nice decomposition or at least nice descriptions.

Our result will be used in the decomposition of radiant affine 3-manifolds, which are 3-manifolds with flat affine structure whose affine holonomy groups fix common points of the affine space (see [14]). This is the decomposition in Thurston’s sense as these manifolds are shown to be Seifert spaces with Euler number zero. In particular, we will be proving there the Carrière conjecture (see [9]) that every radiant affine 3-manifold admits a total section to its radial flow, with the help from Barbot’s work [3], [4] (also see his survey article [2]). This will result in the classification of radiant affine 3-manifolds.

Let us state our theorems more precisely. Let $T$ be an $(i+1)$-simplex in an affine space $\mathbb{R}^n$, $i + 1 < n$, with sides $F_1, F_2, \ldots, F_{i+2}$. A real projective manifold is said to be $i$-convex if every real projective immersion

$$T^n \cup F_2 \cup \cdots \cup F_{i+2} \to M$$

extends to one from $T$ itself.
Theorem 1.1 (Main). — Suppose that $M$ is a compact real projective $n$-manifold with empty or totally geodesic boundary. If $M$ is not $(n-1)$-convex, then $M$ includes a compact concave affine $n$-submanifold $N$ of type $I$ or $II$ or $M^{o}$ includes the canonical two-faced $(n-1)$-submanifold of type $I$ or $II$.

We will define the term “two-faced $(n-1)$-submanifolds of type $I$ and $II$” in Definitions 6.5 and 7.7 which arise in separate constructions. But they are totally geodesic and are quotients of open domains in the affine space by groups of projective transformations and are canonically defined. A two-dimensional example with a nontrivial splitting is given in Example 7.9. We define the term concave affine $n$-submanifold in Definition 9.1: A concave affine $n$-manifold $M$ is a real projective manifold with concave boundary such that its cover is a union of overlapping $n$-crescents. The manifold-interior $M^{o}$ of a concave affine manifold admits a projectively equivalent affine structure of very special nature. We expect them to be very limited. A so-called $n$-crescent is a convex $n$-ball whose bounding sides except one is in the “infinity” of the completion of the universal or holonomy cover (see Definition 3.6). Their interiors are projectively diffeomorphic to either a half-space or an open hemisphere. They are really generalization of affine half-spaces as one of the side is at “infinity” or “missing”.

Let $A$ be a properly imbedded $(n-1)$-manifold in $M^{o}$, which may or may not be two-sided and not necessarily connected or totally geodesic. The so-called splitting $S$ of $M$ along $A$ is obtained by completing $M - N$ by adding boundary which consists of either the union of two disjoint copies of components of $A$ or double covers of components of $A$ (see the beginning of Chapter 10).

A manifold $N$ decomposes into manifolds $N_{1}, N_{2}, \ldots$ if there exists a properly imbedded $(n-1)$-submanifold $\Sigma$ so that $N_{i}$ are components of the manifold obtained from splitting $M$ along $\Sigma$; $N_{1}, N_{2}, \ldots$ are said to be the resulting manifolds of the decomposition.

Corollary 1.2. — Let $M$ be a compact real projective $n$-manifold with empty or totally geodesic boundary. Suppose that $M$ is not $(n-1)$-convex. Then

1. after splitting $M$ along the two-faced $(n-1)$-manifold $A_{1}$ arising from hemispheric $n$-crescents, the resulting manifold $M^{s}$ decomposes into compact concave affine manifolds of type $I$ and real projective $n$-manifolds with totally geodesic boundary which does not include any compact concave affine manifolds of type $I$.

2. We let $N$ be the disjoint union of the resulting manifolds of the above decomposition other than concave affine ones. After cutting $N$ along the two-faced $(n-1)$-manifold $A_{2}$ arising from biaxial $n$-crescents, the resulting manifold $N^{s}$ decomposes into maximal compact concave affine manifolds of type $II$ and real projective $n$-manifolds with convex boundary which is $(n-1)$-convex and includes no compact concave affine manifold of type $II$.

Furthermore, $A_{1}$ and $A_{2}$ are canonically defined and the decomposition is also canonical in the following sense: If $M^{s}$ equals $N \cup K$ for $K$ the union of compact concave affine manifolds of type $I$ in $M^{s}$ and $N$ the closure of the complement of $K$ includes
no compact concave affine manifolds of type I, then the above decomposition agree with the decomposition into components of submanifolds in (1). If $N^s$ equals $S \cup T$ for $T$ the finite disjoint union of maximal compact concave affine manifolds of type II in $N^s$ and $S$ the closure of the complement of $T$ that is $(n-1)$-convex and includes no compact concave affine manifold of type II, then the decomposition agrees with the decomposition into components of submanifolds in (2).

By a *maximal* compact concave affine manifold of type II, we mean one which is not a proper subset of another compact concave affine manifold of type II. If $A_1 = \emptyset$, then we define $M^s = M$ and if $A_2 = \emptyset$, then define $N^s = N$.

We note that $M$, $M^s$, $N$, and $N^s$ have totally geodesic or empty boundary, as we will see in the proof. The final decomposed pieces of $N^s$ are not so. Concave affine manifolds of type II have in general boundary concave seen from their inside and the $(n-1)$-convex real projective manifolds have convex boundary seen from inside (see Chapter 3).

Compare this corollary with what we have proved in [10] and [11] in the language of this paper, as the term "decomposition" is used somewhat differently there by not allowing one-sided closed geodesics to be used for decomposition.

**Theorem 1.3.** — Let $\Sigma$ be a compact real projective surface with totally geodesic or empty boundary. Suppose $\chi(\Sigma) < 0$. Then $\Sigma$ decomposes along the union of disjoint simple closed curves into convex real projective surfaces.

Our Corollary 1.2 is strong enough to imply Theorem 1.3, but we need to work out the classification of concave affine 2-manifolds to do so.

This monograph will be written as self-contained as possible on projective geometry and will use no highly developed machinery but will use perhaps many aspects of discrete group actions and geometric convergence in the Hausdorff sense joined in a rather complicated manner. Objects in this papers are all very concrete ones. To grasp these ideas, one only needs to have some graduate student in geometry understanding and visualization of higher-dimensional projective and spherical geometry. The main methods are extended from those already used in dimension two.

We work on $n \geq 2$ case although $n = 2$ case was more completely answered in the earlier papers [10] and [11] (see Theorem 1.3). The point where this monograph improves the papers [10] and [11] even in $n = 2$ case is that we will be introducing the notion of two-faced submanifolds which makes decomposition easier to understand.

A *holonomy cover* of $M$ is given as the cover of $M$ corresponding to the kernel of the holonomy homomorphism. We often need not look at the universal cover but the holonomy cover as it carries all information and we can define the developing map and holonomy homomorphism from it. The so-called Kuiper completion or projective completion of the universal or holonomy cover is the completion with respect to a metric pulled from $S^n$ by a developing map, as was introduced by Kuiper for conformally flat manifolds (see Kuiper [25]).

In Part I, we give an introduction to projective geometry on spheres and the Kuiper completions of real projective manifolds. In Chapter 2, we will give preliminary definitions and define and classify convex sets in $S^n$. We also discuss the geometric
limit of a sequence of convex balls. In Chapter 3, we discuss the Kuiper or projective completions \( M \) or \( M_h \) of the universal cover \( \hat{M} \) or the holonomy cover \( M_h \) respectively and convex subsets of them, and discuss how two convex subsets may intersect, showing that in the generic case they can be read from their images in \( S^n \). We also introduce “dipping intersection”. This is when we can realize the intersection of two convex balls as the closure of a component of a ball removed with a side of the other ball. We finally discuss the convergence of sequences of convex balls in the Kuiper completions.

In Part II, we will prove main results of this paper. The main focus in this paper is to get good geometric objects in the universal cover of \( M \). Loosely speaking, we illustrate our plan as follows:

(i) For a compact manifold \( M \) which is not \((n-1)\)-convex, obtain an \( n \)-crescent in \( M_h \).

(ii) Divide into two cases where \( M_h \) includes hemispheric \( n \)-crescents and where \( n \)-crescents are always bihedral.

(iii) We derive a certain equivariance properties of hemispheric \( n \)-crescents or the unions of a collection of bihedral \( n \)-crescents equivalent to each other under the equivalence relation generated by the overlapping relation. That is, we show that any two of such sets either agree, are disjoint, or meet only in the boundary.

(iv) We show that the boundary where the two collections meet covers a closed codimension-one submanifold called the two-faced submanifolds. If we split \( M \) along these, then the collection is now truly equivariant. From the equivariance, we obtain submanifolds covered by them called the concave affine manifolds. This completes the proof of the Main Theorem.

(v) Apply the Main Theorem in sequence to prove Corollary 1.2: that is, we split along the two-faced manifolds and obtain concave affine manifolds for hemispheric \( n \)-crescent case and then bihedral \( n \)-crescent case.

In Chapter 4, we prove a central theorem that given a real projective manifold which is not \((n-1)\)-convex, we can find an \( n \)-crescent in the projective completion. The argument is the blowing up or pulling back argument as we saw in [10].

In Chapter 5, we generalize the transversal intersection of crescents to that of \( n \)-crescents (see [10]). This shows that they intersect in a manageable manner so that their sides in the ideal set extend each other and the remaining sides intersect transversally.

In Chapter 6, when \( M_h \) includes a hemispheric \( n \)-crescent, we show how to obtain a two-faced \((n-1)\)-submanifold. This is accomplished by the fact that two hemispheric crescents are either disjoint, equal, or meet only at the boundary, i.e., at a totally geodesic \((n-1)\)-manifold which covers a closed totally geodesic \((n-1)\)-submanifold in \( M \), a so-called two-faced submanifold. In Chapter 7, we assume that \( M_h \) includes no hemispheric \( n \)-crescent but includes bihedral \( n \)-crescents. We define equivalence classes of bihedral \( n \)-crescents. Two bihedral \( n \)-crescents are equivalent if there exists a chain of bihedral \( n \)-crescents overlapping with the next ones in the chain. This enables us to define \( \Lambda(R) \) the union of \( n \)-crescents equivalent to a given \( n \)-crescent
Given \( \Lambda(R) \) and \( \Lambda(S) \) for two \( n \)-crescents \( R \) and \( S \), they are either disjoint, equal, or meet at a totally geodesic \((n - 1)\)-submanifold. We obtain a two-faced \((n - 1)\)-submanifold from the totally geodesic \((n - 1)\)-submanifolds.

In Chapter 8, we show what happens to \( n \)-crescents if we take submanifolds or splits manifolds in the corresponding completions of the holonomy cover. They are all preserved.

In Chapter 9, we prove the Main Theorem: If there is no two-faced submanifold of type I, then two hemispheric \( n \)-crescents are either disjoint or equal. The union of all hemispheric \( n \)-crescents left-invariant by deck transformations and hence covers a submanifold in \( M \), a finite disjoint union of compact concave affine manifolds of type I. If there is no two-faced submanifold of type II, then \( \Lambda(R) \) and \( \Lambda(S) \) for two \( n \)-crescents \( R \) and \( S \) are either disjoint or equal. Again since the deck transformation group acts on the union of \( \Lambda(R) \) for all \( n \)-crescents \( R \), the union covers a manifold in \( M \), a finite disjoint union of compact concave affine manifolds of type II.

In Chapter 10, we prove Corollary 1.2; we decompose real projective manifolds. We show that when we have a two-faced submanifold, we can cut \( M \) along these. The result does not have a two-faced submanifold and hence can be decomposed into \((n - 1)\)-convex ones and properly concave affine manifolds as in Chapter 9.

In Chapter 11, we will show some consequence or modification of our result for Lie groups with left-invariant real projective or affine structures.

A real projective structure on a Lie group is left-invariant if left-multiplications preserve the real projective structure. The methods of the following theorem is also applicable to real projective structures on homogeneous manifolds invariant with respect to proper group actions (see Theorem 11.3).

**Theorem 1.4.** — Let \( G \) be a Lie group with left-invariant real projective structure. Then either \( G \) is \((n - 1)\)-convex or its universal cover \( \tilde{G} \) is projectively diffeomorphic to the universal cover of the complement of a closed convex set in \( \mathbb{R}^n \) with induced real projective structure.

The \((n - 1)\)-convexity of affine structures are defined similarly, and this theorem easily translates to one on affine Lie groups:

**Corollary 1.5.** — Suppose that \( G \) has a left-invariant affine structure. Then either \( G \) is \((n - 1)\)-convex or \( \tilde{G} \) is affinely diffeomorphic to the universal cover of the complement of a closed convex set in \( \mathbb{R}^n \) with induced affine structure.

Part III consists of two appendices: In Appendix A, we show that 3-manifolds with homogeneous Riemannian geometric structures admit canonical real projective structures or product real projective structures using results of Molnár [26]. We show that a real projective manifold is convex if and only if it is a quotient of a convex domain in \( S^n \). In Appendix B, we study some questions on shrinking sequences of convex balls in \( S^n \) that are needed in Chapter 4.
In this chapter, we will discuss somewhat slowly the real projective geometry of \( \mathbb{RP}^n \) and the sphere \( S^n \), and discuss convex subsets of \( S^n \). We will give classification of convex subsets and give topological properties of them. We end with the geometric convergence of convex subsets. (We assume that the reader is familiar with convex sets in affine spaces, which are explained in Berger [7] and Eggleston [20] in detailed and complete manner.)

The real projective space \( \mathbb{RP}^n \) is the quotient space of \( \mathbb{R}^{n+1} - \{0\} \) by the equivalence relation \( x \sim y \) if \( x = sy \) for two nonzero vectors \( x \) and \( y \) and a nonzero real number \( s \). The group \( \text{GL}(n+1, \mathbb{R}) \) acts on \( \mathbb{R}^{n+1} - \{0\} \) linearly and hence on \( \mathbb{RP}^n \), but not effectively. However, the group \( \text{PGL}(n+1, \mathbb{R}) \) acts on \( \mathbb{RP}^n \) effectively. The action is analytic, and hence any element acting trivially in an open set has to be the identity transformation. (We will assume that \( n \geq 2 \) for convenience.)

Real projective geometry is a study of the invariant properties of the real projective space \( \mathbb{RP}^n \) under the action of \( \text{PGL}(n+1, \mathbb{R}) \). Given an element of \( \text{PGL}(n+1, \mathbb{R}) \) we identify it with the corresponding projective automorphism of \( \mathbb{RP}^n \).

By a real projective manifold, we mean an \( n \)-manifold with a maximal atlas of charts to \( \mathbb{RP}^n \) where the transition functions are projective. This lifts all local properties of real projective geometry to the manifold. A real projective map is an immersion from a real projective \( n \)-manifold to another one which is projective under local charts. More precisely, a function \( f : M \rightarrow N \) for two real projective \( n \)-manifolds \( M \) and \( N \) is real projective if it is continuous and for each pair of charts \( \phi : U \rightarrow \mathbb{RP}^n \) for \( M \) and \( \psi : V \rightarrow \mathbb{RP}^n \) for \( N \) such that \( U \) and \( f^{-1}(V) \) overlap, the function

\[
\psi \circ f \circ \phi^{-1} : \phi(U \cap f^{-1}(V)) \rightarrow \psi(f(U) \cap V)
\]

is a restriction of an element of \( \text{PGL}(n+1, \mathbb{R}) \) (see Ratcliff [28]).

It will be very convenient to work on the simply connected sphere \( S^n \) the double cover of \( \mathbb{RP}^n \) as \( S^n \) is orientable and it is easier to study convex sets. We may identify the standard unit sphere \( S^n \) in \( \mathbb{R}^{n+1} \) with the quotient space of \( \mathbb{R}^{n+1} - \{0\} \) by the
equivalence relation \( \sim \) given by \( x \sim y \) if \( x = sy \) for nonzero vectors \( x \) and \( y \) and \( s > 0 \).

As above \( GL(n+1, \mathbb{R}) \) acts on \( S^n \). The subgroup \( SL_{\pm}(n+1, \mathbb{R}) \) of linear maps of determinant \( \pm 1 \) acts on \( S^n \) effectively. We see easily that \( SL_{\pm}(n+1, \mathbb{R}) \) is a double cover of \( PGL(n+1, \mathbb{R}) \). We denote by \( Aut(S^n) \) the isomorphic group of automorphisms of \( S^n \) induced by elements of \( SL_{\pm}(n+1, \mathbb{R}) \).

Since \( \mathbb{R}P^n \) has an obvious chart to itself, namely the identity map, it has a maximal atlas containing this chart. Hence, \( \mathbb{R}P^n \) has a real projective structure. Since \( S^n \) is a double cover of \( \mathbb{R}P^n \), and the covering map \( p \) is a local diffeomorphism, it follows that \( S^n \) has a real projective structure. \( S^n \) with this canonical real projective structure is said to be a \textit{real projective sphere}. We see easily that each element of \( Aut(S^n) \) are real projective maps. Conversely, each real projective automorphism of \( S^n \) is an element of \( Aut(S^n) \) as the actions are locally identical with those of elements of \( Aut(S^n) \).

There is a following convenient commutative diagram:

\[
\begin{align*}
S^n & \xrightarrow{g} S^n \\
\downarrow p & \downarrow p \\
\mathbb{R}P^n & \xrightarrow{g'} \mathbb{R}P^n
\end{align*}
\]

where given a real projective automorphism \( g \), a real projective map \( g' \) always exists and given \( g' \), we may obtain \( g \) unique up to the antipodal map \( A_{S^n} \) which sends \( x \) to its antipodal point \( x^{-} \) for each unit vector \( x \) in \( S^n \).

The standard sphere has a standard Riemannian metric \( \mu \) of curvature 1. We denote by \( d \) the path-metric on \( S^n \) induced from \( \mu \). The geodesics of this metric are paths on a great circles parameterized by \( d \)-length. This metric is projectively flat, and hence geodesics of the metric agree with projective geodesics up to choices of parameterization.

A \textit{convex line} is an embedded geodesic in \( S^n \) of \( d \)-length less than or equal to \( \pi \). A \textit{convex subset} of \( S^n \) is a subset such that any two points of \( A \) are connected by a convex segment in \( A \). A \textit{simply convex subset} of \( S^n \) is a convex subset such that every pair of points are connected by a convex segment of \( d \)-length less than \( \pi - \epsilon \) for a positive number \( \epsilon \). (Note that all these are projectively invariant properties.) A singleton, i.e., the set consisting of a point, is convex and simply convex.

A \textit{great \( i \)-dimensional sphere} is the set of points antipodal to each other. This is not convex. A \textit{great \( i \)-dimensional sphere} in \( S^n \) for \( i \geq 1 \) is convex but not simply convex. An \textit{i-dimensional hemisphere}, \( i \geq 1 \), is the closure of a component of a great \( i \)-sphere \( S^i \) removed with a great \( (i-1) \)-sphere \( S^{i-1} \) in \( S^i \). It is a convex but not simply convex. A \textit{0-dimensional hemisphere} is simply a singleton.

Given a codimension one subspace \( \mathbb{R}P^{n-1} \) of \( \mathbb{R}P^n \), the complement of \( \mathbb{R}P^n \) can be identified with an affine space \( \mathbb{R}^n \) so that geodesic structures agree, i.e., the projective geodesics are affine ones and vice versa up to parameterization. Given an affine space \( \mathbb{R}^n \), we can compactify it to a real projective space \( \mathbb{R}P^n \) by adding points (see Berger [7]). Hence the complement \( \mathbb{R}P^n - \mathbb{R}P^{n-1} \) is called an \textit{affine patch}. An open \( n \)-hemisphere in \( S^n \) maps homeomorphic onto \( \mathbb{R}P^n - \mathbb{R}P^{n-1} \) for a subspace \( \mathbb{R}P^{n-1} \). Hence, the open \( n \)-hemisphere has a natural affine structure of \( \mathbb{R}^n \) whose
geodesic structure is same as that of the projective structure. An open $n$-hemisphere is sometimes called an affine patch.

A subset of $\mathbb{R}^n$ convex in the affine sense is convex in $\mathbb{S}^n$ by our definition when $\mathbb{R}^n$ is identified with the open $n$-hemisphere in this manner.

We give a definition given in [28]: A pair of points $x$ and $y$ is proper if they are not antipodal. A minor geodesic connecting a proper pair $x$ and $y$ is the shorter path in the great circle passing through $x$ and $y$ with boundary $x$ and $y$.

The following proposition shows the equivalence of our definition to one given in [28] except for pairs of antipodal points.

**Proposition 2.1.** A set $A$ is a convex set or a pair of antipodal points if and only if for each proper pair of points $x, y$ in $A$, $A$ includes a minor geodesic $\overline{xy}$ in $A$ connecting $x$ and $y$.

**Proof.** If $A$ is convex, then given two proper pair of points the convex segment in $A$ connecting them is clearly a minor geodesic. A pair of antipodal points has no proper pair.

Conversely, let $x$ and $y$ be two points of $A$. If $x$ and $y$ are proper then since a minor geodesic is convex, we are done. If $x$ and $y$ are antipodal, and $A$ equals $\{x, y\}$, then we are done. If $x$ and $y$ are antipodal, and there exists a point $z$ in $A$ distinct from $x$ and $y$, then $A$ includes the minor segment $\overline{zx}$ and $\overline{zy}$ and hence $\overline{zx} \cup \overline{zy}$ is a convex segment connecting $x$ and $y$; $A$ is convex. \qed

By the above proposition, we see that our convex sets satisfy the properties in Section 6.2 of [28]. Let $A$ be a nonempty convex subset of $\mathbb{S}^n$. The dimension of $A$ is defined to be the least integer $m$ such that $A$ is included in a great $m$-sphere in $\mathbb{S}^n$. If dim($A$) = $m$, then $A$ is included in a unique great $m$-sphere which we denote by $\langle A \rangle$. The interior of $A$, denoted by $A^\circ$, is the topological interior of $A$ in $\langle A \rangle$, and the boundary of $A$, denoted by $\partial A$, is the topological boundary of $A$ in $\langle A \rangle$. The closure of $A$ is denoted by $\text{Cl}(A)$ and is a subset of $\langle A \rangle$. $\text{Cl}(A)$ is convex and so is $A^\circ$.

Moreover, the intersection of two convex sets is either convex or is a pair of antipodal points by the above proposition. Hence, the intersection of two convex sets is convex if it contains at least three points, it contains a pair of nonantipodal points, or one of the sets contains no pair of antipodal points.

A **convex hull** of a set $A$ is the minimal convex set including $A$. A **side** of a convex set $A$ is a maximal convex subset of $\partial A$. A **polyhedron** is a convex set with finitely many sides.

**Lemma 2.2.** Let $A$ be a convex set. $A^\circ$ is not empty unless $A$ is empty.

**Proof.** Let $\langle A \rangle$ have dimension $k$. Then $A$ has to have at least $k + 1$ points $p_1, \ldots, p_{k+1}$ in general position as unit vectors in $\mathbb{R}^{n+1}$ since otherwise every $(k+1)$-tuple of vectors are dependent and $A$ is a subset of a great sphere of lower dimension. The convex hull of the points $p_1, \ldots, p_{k+1}$ is easily shown to be a spherical simplex with vertices $p_1, \ldots, p_{k+1}$. The simplex is obviously a subset of $A$, and the interior of the simplex is included in $A^\circ$. \qed

We give the classification of convex sets in the following two propositions.
**Proposition 2.3.** — Let $A$ be a convex subset of $S^n$. Then $A$ is one of the following sets:

1. a great sphere $S^m$, $1 \leq m \leq n$,
2. an $m$-dimensional hemisphere $H^m$, $0 \leq m \leq n$,
3. a proper convex subset of an $i$-hemisphere $H^m$.

**Proof.** — We will prove by induction on dimension $m$ of $\langle A \rangle$. The theorem is obvious for $m = 0, 1$. Suppose that the theorem holds for $m = k - 1$, $k \geq 2$. Suppose now that the dimension of $A$ equals $m$ for $m = k$. Let us choose a hypersphere $S^{m-1}$ in $\langle A \rangle$ intersecting with $A^o$. Then $A_1 = A \cap S^{m-1}$ is as one of the above (1), (2), (3). The dimension of $A_1$ is at least one, i.e., $m - 1 \geq 1$. Suppose $A_1 = S^{m-1}$. As $A^o$ has two points $x, y$ respectively in components of $\langle A \rangle - S^{m-1}$, taking the union of segments from $x$ to points of $S^{m-1}$, and segments from $y$ to points of $S^{m-1}$, we obtain that $A = \langle A \rangle$.

If $A_1$ is as in (2) or (3), then choose an $(m - 1)$-hemisphere $H$ including $A_1$ with boundary a great $(m - 2)$-sphere $\partial H$. Consider the collection $\mathcal{P}$ of all $(m - 1)$-hemispheres including $\partial H$. Then $\mathcal{P}$ has a natural real projective structure of a great circle, and let $A'$ be the set of the $(m - 1)$-hemispheres in $\mathcal{P}$ whose interior meets $A$. Then since a convex segment in $\langle A \rangle - \partial H$ projects to a convex segment in the circle $\mathcal{P}$, it follows that $A'$ has the property that any proper pair of points of $A'$ is connected by a minor geodesic, and by Proposition 2.1 $A'$ is either a pair of antipodal points or a convex subset.

Let $H^-$ denote the closure of the complement of $\langle A_1 \rangle - H$. Then the interior of $H^-$ do not meet $A$ as it does not meet $A_1$. Hence $A'$ is a subset of $\mathcal{P} - \{H^-, H\}$.

If $A'$ is a pair of antipodal points, then $A'$ must be $\{H, H^-\}$, and this is a contradiction. Since $A'$ is a proper convex subset of $\mathcal{P}$, $A'$ must be a convex subset of a 1-hemisphere $I$ in $\mathcal{P}$. This means that only the interior of $(m - 1)$-hemispheres in $I$ meets $A$, and there exists an $m$-hemisphere in $\langle A \rangle$ including $A$. Thus $A$ either equals this $m$-hemisphere or a proper convex subset of it. \qed

We say that a subset of a real projective manifold satisfies the **Kobayashi's criterion** if there is no non-constant projective map from the real line $\mathbb{R}$ to it. (A convex open domain in $S^n$ satisfying Kobayashi’s criterion has a complete Hilbert metric by Proposition 3.20 [24].)

Given a convex compact subset $A$ of $S^n$ the following statements are equivalent:

- $A$ satisfies Kobayashi’s criterion.
- $A$ does not include a line whose $d$-length equals $\pi$.
- $A$ does not include a pair of points antipodal to each other.

Let $A$ be a convex subset of an $i$-hemisphere $H^i$ for $i \geq 1$. Assume that $A$ does not satisfy Kobayashi’s criterion. Then there are great spheres of dimension $\geq 0$ in $\text{Cl}(A)$. Since great spheres in $H^i$ are subsets of $\partial H^i$, they are included in $\partial A \cap \partial H^i$.

Given two great spheres $S^j$ and $S^k$ in $A$ for $0 \leq j, k \leq i - 1$, the geometry of $H^i$ and the convexity of $A$ easily imply that there exists a great sphere $S^l$ with $j, k < l \leq i - 1$ including the both spheres. (Note that if $k = i - 1$, then $A$ equals $H^i$.)
CHAPTER 2. CONVEX SUBSETS OF THE REAL PROJECTIVE SPHERE

**Proposition 2.4.** — Let $A$ be a convex subset of an $i$-dimensional hemisphere $H^i$ for $i \geq 1$. Then exactly one of the following holds:

- $\partial A$ includes a unique maximal great $j$-sphere $S^j$ for some $0 \leq j \leq i - 1$, which must be in $\partial H^i$ and the closure of $A$ is the union of $(j + 1)$-hemispheres with common boundary $S^j$, or
- $A$ is a simply convex subset of $H^i$, in which case $A$ can be realized as a bounded convex subset of perhaps another open $i$-hemisphere $K^i$ identified with an affine space $\mathbb{R}^i$.

**Proof.** — We assume without loss of generality that $A$ is closed by taking the closure of $A$ if necessary. The first item is proved in the above paragraph since the second statement of the first item simply follows from convexity of $A$.

If $A$ includes no pair of antipodal points, then let $m$ be the dimension of $\langle A \rangle$ and we do the induction over $m$. If $m = 0, 1$, then the second item is obvious. Suppose we have the second item holding for $m = k - 1$, where $k \geq 2$. Now let $m = k$, and choose a great sphere $S^{m-1}$ meeting $A^o$, and let $A_1 = A \cap S^{m-1}$. Since $A_1$ is another simply convex set, $A_1$ is a bounded convex subset of an open $(m - 1)$-hemisphere $K$ identified as an affine space $\mathbb{R}^{m-1}$. Hence $A_1$ does not meet $\partial K$. As in the proof of Proposition 2.3, we let $\mathcal{P}$ be the set of all $(m - 1)$-hemispheres with boundary in $\partial K$, which has a natural real projective structure of a great circle. As in the proof, we see that the subset $A'$ of $\mathcal{P}$ consisting of hemispheres whose interior meets $A$ is a convex subset of a 1-hemisphere in $\mathcal{P}$. The boundary of $A'$ consists of two hemispheres $H_1$ and $H_2$. Since $A'$ is connected, $H_1$ and $H_2$ bound a convex subset $L$ in $\langle A \rangle$, and $H_1$ and $H_2$ meet in a $\mu$-angle less than or equal to $\pi$.

If the angle between $H_1$ and $H_2$ equals $\pi$, then $H_1 \cup H_2$ is a great $(m - 1)$-sphere, and $H_1^o$ and $H_2^o$ contains two points $p, q$ of $A$ respectively which are not antipodal. Since $A$ is convex, $\overline{pq}$ is a subset of $A$; since $p$ and $q$ is not antipodal, $\overline{pq}$ meets $\partial K$ by geometry, a contradiction.

Since the angle between $H_1$ and $H_2$ is less than $\pi$, it is now obvious that there exists an $m$-hemisphere $H$ including $A$ and meeting $L$ only at $\partial K$. Hence $A$ is a convex subset of $H^o$. Since $A$ is compact, $A$ is a bounded convex subset of $H^o$. \(\Box\)

An $m$-bihedron in $S^m$ is the closure of a component of a great sphere $S^m$ removed with two great spheres of dimension $m - 1$ in $S^m$ ($m \geq 1$). A 1-bihedron is a simply convex segment.

**Lemma 2.5.** — A compact convex subset $K$ of $S^n$ including an $(n - 1)$-hemisphere is either the sphere $S^n$, a great $(n - 1)$-sphere, an $n$-hemisphere, an $n$-bihedron, or the $(n - 1)$-hemisphere itself.

**Proof.** — Let $H$ be the $(n - 1)$-hemisphere in $K$ and $s$ the great circle perpendicular to $H$ at the center of $H$. Then since $K$ is convex, $s \cap K$ is a convex subset of $s$ or a pair of antipodal point as in the proof of Proposition 2.3. If $s \cap K = s$, then every segment from a point of $s$ to a point of $H$ belongs to $K$ by convexity. Thus, $K = S^n$. Depending on whether $s \cap K$ is a point, a pair of antipodal points, a 1-hemisphere
or a simply convex segment, $K$ is $H$, a great $(n-1)$-sphere, an $n$-hemisphere or an $n$-bihedron.

**Proposition 2.6.** — Let $A$ be a convex $m$-dimensional subset of $S^n$ other than a great sphere. Then $A^o$ is homeomorphic to an open $m$-ball, $\text{Cl}(A)$ the compact $m$-ball, and $\partial A$ to the sphere of dimension $m-1$.

**Proof.** — We can generalize Section 11.3.1 of Berger [7] to prove this proposition. □

Let $A$ be an arbitrary subset of $S^n$ and $x$ a point of the topological boundary $\text{bd}A$ of $A$. A supporting hypersphere $L$ for $A$ is a great $(n-1)$-sphere containing $x$ in $A$ such that the two closed hemispheres determined by $L$ includes $A$ and $x$ respectively. We say that $L$ is the supporting hypersphere for $A$ at $x$.

**Proposition 2.7.** — Let $A$ be a convex subset of $S^n$, other than $S^n$ itself. Then for each point $x$ of $\partial A$, there exists a supporting hypersphere for $A$ at $x$.

**Proof.** — If the dimension $i$ of $A$ is 0, this is trivial. Assume $i \geq 1$. If $A$ is a great $i$-sphere or an $i$-hemisphere $i \geq 1$, it is obvious. If not, then $A$ is included in an $i$-hemisphere, say $H$. Then $A^o$ is a convex subset of the affine space $H^o$. If $x \in H^o$, there exists a supporting hyperplane $K$ for $A^o$ at $x$ by Proposition 11.5.2 of [7]. The hyperplane $K$ equals $L \cap H^o$ for a great $(i-1)$-sphere $L$ in $A^o$. Thus any great $(n-1)$ sphere $P$ meeting $A^o$ at $L$ is the supporting hypersphere for $A$ at $x$. If $x \in \partial H$, then the conclusion is obvious. □

We define the Hausdorff distance $d^H$ between all compact subsets of $S^n$: We say that two compact subsets $X, Y$ have distance $d^H$ less than $\epsilon$, if $X$ is in an $\epsilon$-$d$-neighborhood of $Y$ and $Y$ is in one of $X$. This defines a metric on the space of all compact subsets of $S^n$.

Suppose that a sequence of compact sets $K_i$ converges to $K_\infty$. Then it is well-known that $x$ belongs to $K_\infty$ if and only if $x$ is a limit of a sequence $\{x_i\}$, $x_i \in K_i$; if $x \in K_\infty$, then by definition for any positive number $\epsilon$, there exists an $N$ so that for $i > N$, $K_i$ contains a point $x_i$ so that $d(x,x_i) < \epsilon$. Also, given a point $x$ of $S^n$, if a sequence $x_i \in K_i$ converges to $x$, then $x$ lies in $K_\infty$. If otherwise, $x$ is at least $\delta$ away from $K_\infty$ for $\delta > 0$, and so the $\delta/2$-$d$-neighborhood of $K_\infty$ is disjoint from an open neighborhood $J$ of $x$. But since $x_i \in J$ for $i$ sufficiently large, this contradicts $K_i \to K_\infty$.

**Proposition 2.8.** — Given a sequence of compact convex subsets $K_i$ of $S^n$, we can always choose a subsequence converging to a subset $K_\infty$. $K_\infty$ is compact and convex. Also the following hold:

- If $K_i$ are great $i$-spheres, then $K_\infty$ is a great $i$-sphere.
- If $K_i$ are $i$-hemispheres, that $K_\infty$ is an $i$-hemisphere.
- If $K_i$ are $i$-bihedrons, then $K_\infty$ is either an $i$-hemisphere, an $i$-bihedron, or an $(i-1)$-hemisphere.
- If $K_i$ are $i$-balls, then $K_\infty$ is a convex ball of dimension less than or equal to $i$. 
CHAPTER 2. CONVEX SUBSETS OF THE REAL PROJECTIVE SPHERE

Proof. — The first statement follows from the well-known compactness of the spaces of compact subsets of compact metric spaces under Hausdorff metrics.

For each point $x$ of $K_\infty$, there exists a sequence $x_i \in K_i$ converging to $x$. Choose arbitrary two distinct points $x$ and $y$ of $K_\infty$, and sequences $x_i \in K_i$ and $y_i \in K_i$ converging to $x$ and $y$ respectively. Then there exists a segment $\overline{x_iy_i}$ of $d$-length $\leq \pi$ in $K_i$ connecting $x_i$ and $y_i$. Since the sequence of $\overline{x_iy_i}$ is a sequence of compact subsets of $S^n$, we may assume that a subsequence converges to a compact subset $L$ of $S^n$. By the above paragraph $L \subset K_\infty$. Since 1-bihedrons and 1-hemispheres are nothing but convex segments, the second and third items imply that $L$ is a convex segment. Thus $K_\infty$ is convex.

(1) A great $i$-sphere is defined by $n - i$ number of dual $d$-orthonormal vectors of $\mathbb{R}^n$. Let $\{s_i^1, \ldots, s_i^{n-k}\}$ for $i = 1, 2, \ldots$ to be the set of dual vectors for a great sphere $K_i$. Then a point $x$ belongs to $K_\infty$ if and only if it is a limit of a sequence of points $x_i \in K_i$. Hence, $x$ belongs to $K_\infty$ if and only if $x$ is zero under the set of limit dual vectors. Hence, $K_\infty$ is precisely defined by a set of $(n - i)$-equations and is a great $i$-sphere.

(2) This follows as in (1) using $d$-orthonormal dual vectors defining an $i$-hemisphere.

(3) An $i$-bihedron is defined by $n - i$ $d$-orthonormal vectors defining the great $i$-sphere including it and two $d$-unit vectors which are normal to the $n - i$ vectors but may have an angle with respect to each other.

(4) If $K_i$ are $i$-balls, then $K_i \subset H_i$ for $i$-hemispheres $H_i$. We choose a subsequence $i_j$ of $i$ so that $H_{i_j}$ converges to an $i$-hemisphere $H$. It follows that $K_\infty$ is a subset of $H$ by the paragraph above our proposition since $K_i$ converges to $K_\infty$. Thus, $K_\infty$ is a compact convex subset of $H$, which shows that $K_\infty$ is a convex ball of dimension $\leq i$ by Proposition 2.6.

Remar 2.9. — Contrary to above a sequence of simply convex $i$-balls can converge to an $i$-hemisphere or nonsimply convex $i$-balls. Given a sequence of $i$-balls $K_i$, if $L_i$ is the sequence of maximal great spheres in $K_i$ of dimension $j$, then the limit $K_\infty$ includes the limits of subsequences of $L_i$ and the maximal great sphere for $K_\infty$ has dimension greater than or equal to the limit supremum of the sequence of the dimensions of $L_i$.

Proposition 2.10. — Let $K_i$ be a sequence of convex $n$-balls. If $\dim K_\infty = n$, then we have $\bigcup_{i=1}^\infty K_i \supseteq K_\infty$. In this case $\partial K_i \rightarrow \partial K_\infty$.

The proof follows as in Section 2 of Appendix of [10]. The dimension does not play a role. We will give a shortened proof here for reader's convenience.

Given a great sphere $S^{n-1}$ in $S^n$ and a point $x$ belonging to $S^n - S^{n-1}$, if a geodesic from $x$ to $S^{n-1}$ is perpendicular to $S^{n-1}$, and its $d$-length $\leq \pi/2$, then its $d$-length equals $d(x, S^{n-1})$.

Suppose that $x \in B$ for a convex $i$-ball $B$. Then we have $d(x, \partial B) \leq \pi/2$. We have $d(x, \partial B) = \pi/2$ if and only if $B$ is an $i$-hemisphere of which $x$ is the center.

Lemma 2.11. — Let $A$ and $B$ be two convex $n$-balls in $S^n$. Suppose that $A^{\circ} - B^{\circ}$ contains a point $x$ such that $d(x, \partial A) > 2\epsilon$ for a positive constant $\epsilon$. Then $d^H(A, B) > \epsilon$. 

Proof. — Since \( x \not\in B^o \), an \( n \)-hemisphere \( H \) contains \( x \) and satisfies \( B \cap H^o = \emptyset \) by Proposition 2.7. The proof reduces to the claim that \( A \cap H \) contains a point \( y \) such that \( \text{d}(y, S^n - H^o) > \epsilon \). Let \( \alpha \) be the diameter of \( H \) passing through \( x \). Let \( \beta = \alpha \cap A \). The subset \( \beta \) is a connected segment in the convex \( n \)-ball \( A \cap H \) whose endpoints are contained in \( \partial(A \cap H) \). Since \( \beta \not\ni x \) and at least one of the endpoints of \( \beta \) belongs to \( \partial A \), it follows that \( \text{d-length}(\beta) > 2\epsilon \). Since we have \( \beta \subset \alpha \) and \( 2\epsilon < \pi \), the segment \( \beta \) contains a point \( y \) such that

\[
\epsilon < \text{d}(y, \partial \alpha) \leq \pi/2.
\]

As \( \alpha \) is perpendicular to \( \partial H \), we obtain

\[
\text{d}(y, S^n - H^o) > \epsilon.
\]

\[ \square \]

Proof of Proposition 2.10. — Let \( x \in K^o \). Then \( \text{d}(x, \partial K) > 2\epsilon \) for a positive constant \( 2\epsilon \). Let \( N \) be a positive integer such that \( \text{d}^H(K, K_i) < \epsilon \) whenever \( i > N \). By Lemma 2.11, \( x \in K_i^o \) whenever \( i > N \). Thus we obtain \( \bigcup_{i=1}^\infty K_i^o \supseteq K^o \).

Given two convex \( n \)-balls \( A \) and \( B \), if \( \text{d}^H(A, B) \leq \epsilon \) for a positive real number \( \epsilon \), then \( \text{d}^H(\partial A, \partial B) \leq 2\epsilon \). Suppose that \( \text{d}^H(\partial A, \partial B) > 2\epsilon \). Then either \( \partial A \) contains a point \( x \) such that \( \text{d}(x, \partial B) > 2\epsilon \) or \( \partial B \) contains a point \( y \) such that \( \text{d}(\partial A, y) > 2\epsilon \). It is sufficient to consider the first case: If \( x \not\in B \), then we have \( \text{d}(x, B) > 2\epsilon \) and, hence, \( \text{d}^H(A, B) > 2\epsilon \). If \( x \in B \), then we have \( x \in B^o \) and, by Lemma 2.11, \( \text{d}^H(A, B) > \epsilon \). Both are contradictions.

\[ \square \]
CHAPTER 3

CONVEX SUBSETS IN THE KUIPER COMPLETIONS

In this second chapter, we begin by lifting the development pair to the real projective sphere $S^n$. Then we define the holonomy cover $M_h$ of a real projective manifold using the lifts. To make our discussion more familiar, we will define a completion, called a Kuiper completion or projective completion, by inducing the Riemannian metric of the sphere to the universal cover $\tilde{M}$ or the holonomy cover $M_h$ and then completing them in the Cauchy sense. Then we define the ideal set to be the completion removed with $\tilde{M}$ or $M_h$, i.e., points infinitely far away from points of $\tilde{M}$ or $M_h$.

We will define convex sets in these completions, which are always “isomorphic” to ones in $S^n$. Then we will introduce $n$-crescents, which are convex $n$-balls in the completions where a side or an $(n-1)$-hemisphere in the boundary lies in the ideal sets. We show how two convex subsets of the completion may intersect; their intersection properties are described by their images in $S^n$ under the developing map. Finally, we describe the dipping intersection, the type of intersection which will be useful in this paper, and on which our theory of $n$-crescents depends heavily as we shall see in Chapter 5.

Finally, we discuss when a sequence of convex $n$-balls in the Kuiper complement may share a common open ball in them, the phenomenon which naturally occurs in this paper because of dipping intersection properties. When there exists a common open ball for a sequence of convex $n$-balls, we can find its geometric “limit” and the geometric “limits” of the sequences of their subsets in many cases. (This part is rewritten from the appendix of [10] but for general dimension $n$ which creates no differences.)

Let $M$ be a real projective $n$-manifold. Then $M$ has a development pair $(\text{dev}, h)$ of an immersion $\text{dev} : \tilde{M} \to \mathbb{R}P^n$, called a developing map, and a holonomy homomorphism $h : \pi_1(M) \to \text{PGL}(n+1, \mathbb{R})$ satisfying $\text{dev} \circ \gamma = h(\gamma) \circ \text{dev}$ for every $\gamma \in \pi_1(M)$. Such a pair is determined up to an action of an element $\vartheta$ of $\text{PGL}(n+1, \mathbb{R})$ as follows:

$$\text{(3.1)} \quad (\text{dev}, h(\cdot)) \mapsto (\vartheta \circ \text{dev}, \vartheta \circ h(\cdot) \circ \vartheta^{-1}).$$
Developing maps are obtained by analytically extending coordinate charts in the atlas. The holonomy homomorphism is determined from the chosen developing map. (See Ratcliff [28] for more details.) The development pair characterizes the real projective structure, and hence another way to give a real projective structure to a manifold is to find a pair \((f, k)\) where \(f\) is an immersion \(\hat{M} \to \mathbb{R}P^n\) which is equivariant with respect to the homomorphism \(k\) from the group of deck transformations to \(\text{PGL}(n + 1, \mathbb{R})\).

We assume that the manifold-boundary \(\delta M\) of a real projective manifold \(M\) is \textit{totally geodesic} unless stated otherwise. (Surely, \(M\) may have empty boundary.) This means that for each point of \(\delta M\), there exist an open neighborhood \(U\) and a lift \(\phi : U \to \mathbb{S}^n\) of a chart \(U \to \mathbb{R}P^n\) so that \(\phi(U)\) is a nonempty intersection of a closed \(n\)-hemisphere with a simply convex open set. (By an \(n\)-hemisphere, we mean a closed hemisphere unless we mention otherwise.) \(\delta M\) is said to be \textit{convex} if there exists an open neighborhood \(U\) and a chart \(\phi\) for each point of \(\delta M\) so that \(\phi(U)\) is a convex domain in \(\mathbb{S}^n\). \(\delta M\) is said to be \textit{concave} if there exists a chart \((U, \phi)\) for each point of \(\delta M\) so that \(\phi(U)\) is the complement of a convex open set in an open simply convex subset of \(\mathbb{S}^n\).

We remark that if \(M\) has totally geodesic boundary, then so do all of its covers. The same facts are true for convexity and concavity of boundary. Also, we will need to allow our manifold \(M\) to be a topological manifold with boundary being not smooth, especially when \(\delta M\) is convex or concave. This does not cause any complications as transition functions are smooth, and such manifolds can be considered as topologically imbedded submanifolds of smooth manifolds.

\textbf{Lemma 3.1.} — \textit{Let \(M\) have totally geodesic boundary. Suppose that a connected totally geodesic \((n - 1)\)-submanifold \(S\) of \(M\) of codimension \(\geq 1\) intersects \(\delta M\) in its interior point. Then \(S \subset \delta M\).}

\textbf{Proof.} — The intersection point must be a tangential intersection point. Since \(\delta \hat{M}\) is a closed subset of \(\hat{M}\), the set of intersection of \(S\) and \(\delta \hat{M}\) is an open and closed subset of \(S\). Hence it must be \(S\). \(\square\)

\textbf{Remark 3.2.} — If \(\delta M\) is assumed to be convex, the conclusion holds also. This was done in [10] in dimension 2. The proof for the convex boundary case is the same as the dimension 2.

\textbf{Remark 3.3.} — Given any two real projective immersions \(f_1, f_2 : N \to \mathbb{R}P^n\) on a real projective manifold \(N\), they differ by an element of \(\text{PGL}(n + 1, \mathbb{R})\), i.e., \(f_2 = \zeta \circ f_1\) for a projective automorphism \(\zeta\) as they are charts restricted to an open set, and they must satisfy the equation there, and by analyticity everywhere. Let \(p : \mathbb{S}^n \to \mathbb{R}P^n\) denote the covering map. Given two real projective immersions \(f_1, f_2 : N \to \mathbb{S}^n\), we have that \(p \circ f_1 = \zeta \circ p \circ f_2\) for \(\zeta\) in \(\text{PGL}(n + 1, \mathbb{R})\). By equation 2.1, there exists an element \(\zeta'\) of \(\text{Aut}(\mathbb{S}^n)\) so that \(p \circ \zeta' = \xi \circ p\) where \(\xi\) and \(\Lambda_{\mathbb{S}^n} \circ \zeta'\) are the only automorphisms satisfying the equation. This means that \(p \circ f_1 = \zeta' \circ f_2\) or \(f_1 = \Lambda_{\mathbb{S}^n} \circ \zeta' \circ f_2\), and hence it follows easily that \(f_1 = \zeta' \circ f_2\) or \(f_1 = \Lambda_{\mathbb{S}^n} \circ \zeta' \circ f_2\) by analyticity of developing maps. Hence, any two real projective maps \(f_1, f_2 : N \to \mathbb{S}^n\) differ by an element of \(\text{Aut}(\mathbb{S}^n)\).
We agree to lift our developing map \texttt{dev} to the standard sphere \( S^n \), the double cover of \( \mathbb{R}P^n \), where we denote the lift by \( \texttt{dev}' \). Then for any deck transformation \( \vartheta \) of \( \hat{M} \), we have \( \texttt{dev}' \circ \vartheta = h'(\vartheta) \circ \texttt{dev}' \) by the above remark. Hence \( \vartheta \mapsto h'(\vartheta) \) is a homomorphism, and we see easily that \( h' \) is a lift of \( h \) for the covering homomorphism \( \text{Aut}(S^n) \to \text{PGL}(n+1, \mathbb{R}) \).

The pair \( (\texttt{dev}', h') \) will from now on be denoted by \( (\texttt{dev}, h) \), and they satisfy \( \texttt{dev} \circ \gamma = h(\gamma) \circ \texttt{dev} \) for every \( \gamma \in \pi_1(M) \), and moreover, given a real projective structure, \( (\texttt{dev}, h) \) is determined up to an action of \( \vartheta \) of \( \text{Aut}(S^n) \) as in equation 3.1 by the above remark.

The sphere \( S^n \) has the standard metric \( \mu \) so that its projective structure is projectively equivalent to it; i.e., the geodesics agree. We denote by \( \texttt{d} \) the path-metric induced from \( \mu \). From the immersion \( \texttt{dev} \), we induce a Riemannian metric \( \mu \) of \( \hat{M} \), and let \( \texttt{d} \) denote the induced path-metric on \( \hat{M} \). The Cauchy completion of \((\hat{M}, \texttt{d})\) is denoted by \((\hat{M}, \texttt{d})\), which we say is the \textit{Kuiper completion} or \textit{projective completion} of \( \hat{M} \). We define the ideal set \( \hat{M}_\infty = \hat{M} - \hat{M} \).

These sets are topologically independent of the choice of \( \texttt{dev} \) since the metrics pulled from developing maps are always quasi-isometric to one another, i.e., they differ by an element of \( \text{Aut}(S^n) \) a quasi-isometry of \( S^n \) with metric \( \texttt{d} \).

Naturally, \( \texttt{dev} \) extends to a distance-decreasing map, which we denote by \( \texttt{dev} \) again. Since for each \( \vartheta \in \text{Aut}(S^n) \), \( \vartheta \) is quasi-isometric with respect to \( \texttt{d} \), and each deck transformations \( \varphi \) of \( \hat{M} \) locally mirror the metrical property of \( h(\varphi) \), it follows that the deck transformations are quasi-isometric (see [10]). Thus, each deck transformation of \( \hat{M} \) extends to a self-homeomorphism of \( \hat{M} \). The extended map will be still called a \textit{deck transformation} and will be denoted by the same symbol \( \varphi \) if so was the original deck transformation denoted. Finally, the equation \( \texttt{dev} \circ \vartheta = h(\vartheta) \circ \texttt{dev} \) still holds for each deck transformation \( \vartheta \).

The kernel \( K \) of \( h : \pi_1(M) \to \text{Aut}(S^n) \) is well-defined since \( h \) is well-defined up to conjugation. Since \( \text{dev} \circ \vartheta = \text{dev} \) for \( \vartheta \in K \), we see that \( \text{dev} \) induces a well-defined immersion \( \texttt{dev}' : \hat{M}/K \to S^n \). We say that \( \hat{M}/K \) the \textit{holonomy cover} of \( M \), and denote it by \( M_h \). We identify \( K \) with \( \pi_1(M_h) \). Since any real projective map \( f : M_h \to S^n \) equals \( \vartheta \circ \texttt{dev}' \) for \( \vartheta \in \text{Aut}(S^n) \) by Remark 3.3, it follows that \( \texttt{dev} \circ \varphi \) equals \( h'(\varphi) \circ \texttt{dev} \) for each deck transformation \( \varphi \in \pi_1(M)/\pi_1(M_h) \) and \( h'(\varphi) \in \text{Aut}(S^n) \). Thus, \( \varphi \mapsto h'(\varphi) \) is a homomorphism \( h' : \pi_1(M)/\pi_1(M_h) \to \text{Aut}(S^n) \), which is easily seen to equal \( h' = h \circ \Pi \) for the quotient homomorphism \( \Pi : \pi_1(M) \to \pi_1(M)/\pi_1(M_h) \).

Moreover, by Remark 3.3, \( (\texttt{dev}', h') \) is determined up to an action of \( \vartheta \) in \( \text{Aut}(S^n) \) as in equation 3.1. Conversely, such a pair \( (f, k) \) where \( f : M_h \to S^n \) equivariant with respect to the homomorphism \( k : \pi_1(M)/\pi_1(M_h) \to \text{Aut}(S^n) \) determines a real projective structure on \( M \). From now on, we will denote \( (\texttt{dev}', h') \) by \( (\texttt{dev}, h) \), and call the pair a \textit{development pair}.

Given \( \texttt{dev} \), we may pull-back \( \mu \), and complete the path-metric \( \texttt{d} \) to obtain \( M_h \), the completion of \( M_h \), which is again called a \textit{Kuiper or projective completion}. We define the \textit{ideal set} \( M_{h, \infty} \) to be \( M_h - M_h \). As before the developing map \( \texttt{dev} \) extends to a distance-decreasing map, again denoted by \( \texttt{dev} \), and each deck transformation extends to a self-homeomorphism \( M_h \to M_h \), which we call a \textit{deck transformation} still.
Finally, the equation $\text{dev} \circ \vartheta = h(\vartheta) \circ \text{dev}$ still holds for each deck transformation $\vartheta$.

As an aside, we have the following proposition. A cover $M'$ of $M$ is called developing cover if it admits a real projective immersion to $S^n$. We may define the Kuiper completion $\tilde{M}'$ and ideal set $\tilde{M}'_\infty$ using the metric pulled back from $d$ on $S^n$ using the immersion. These sets are canonically defined regardless of the choice of the immersion.

**Proposition 3.4.** — Let $M'$ be a cover of $M$. Then $M'$ is developing if and only if there is a covering map $g : M' \to M_h$. In this case, each real projective immersion $f : M' \to S^n$ equals $\text{dev} \circ g$ for a developing map $\text{dev}$ of $M_h$.

**Proof.** — The converse is clear. Let $f : M' \to S^n$ be a real projective immersion. Then for any loop in $M'$ maps to a loop in $M$ of trivial holonomy since we may break up $f$ to use it as charts on $M'$ and $M$. Since $\pi_1(M')$ thus injects into the kernel of the holonomy homomorphism $\pi_1(M) \to \text{Aut}(S^n)$, $M'$ covers $M_h$ by a covering map $g$. $\text{dev} \circ g$ is also a projective immersion and must agree with $k \circ f$ for $k \in \text{Aut}(S^n)$ by Remark 3.3. As $k^{-1} \circ \text{dev} : M_h \to S^n$ is a developing map, this completes the proof. 

A subset $A$ of $\tilde{M}$ is a convex segment if $\text{dev}|A$ is an imbedding onto a convex segment in $S^n$. $M$ is convex if given two points of the universal cover $\tilde{M}$, there exists a convex segment in $\tilde{M}$ connecting these two points (see Theorem 4.5). A subset $A$ of

---

**Figure 3.1.** A figure of $M_h$. The thick dark lines indicate $\delta M_h$ and the dotted lines the ideal boundary $M_h,\infty$, and 2-crescents in them in the right. They can have as many “pods” and what looks like “overlaps”. Such pictures happen if we graft annuli into convex surfaces (see Goldman [21]).
$M$ is convex if given points $x$ and $y$ of $A$, $A$ includes a convex segment containing $x$ and $y$. We say that $A$ is a tame subset if it is a convex subset of $M$ or a convex subset of a compact convex subset of $M$. If $A$ is tame, then $\text{dev}|A$ is an imbedding onto $\text{dev}(A)$ and $\text{dev}|\text{Cl}(A)$ for the closure $\text{Cl}(A)$ of $A$ onto a compact convex set $\text{Cl}(\text{dev}(A))$. The interior $A^o$ of $A$ is defined to be the set corresponding to $\text{Cl}(\text{dev}(A))^o$ and the boundary $\partial A$ the subset of $\text{Cl}(A)$ corresponding to $\partial \text{Cl}(\text{dev}(A))$. Note that $\partial A$ may not equal the manifold boundary $\delta A$ if $A$ has a (topological) manifold structure. But if $A$ is a compact convex set, then $\text{dev}(A)$ is a manifold by Proposition 2.6, i.e., a sphere or a ball, and $\partial A$ has to equal $\delta A$. In this case, we shall use $\delta A$ over $\partial A$. A side of a compact convex subset $A$ of $M$ is a maximal convex subset of $\delta A$. A polyhedron is a compact convex subset $A$ of $M$ with finitely many sides.

**Definition 3.5.** — An $i$-ball $A$ in $M$ is a compact subset of $M$ such that $\text{dev}|A$ is a homeomorphism to an $i$-ball (not necessarily convex) in a great $i$-sphere and its manifold interior $A^o$ is a subset of $\hat{M}$. A convex $i$-ball is an $i$-ball that is convex.

A tame set in $\hat{M}$ which is homeomorphic to an $i$-ball is not necessarily an $i$-ball in this sense; that is, its interior may not be a subset of $\hat{M}$. We will say it is a tame topological $i$-ball but not $i$-ball or convex $i$-ball.

We define the terms convex segments, convex subset, tame subset, $i$-ball and convex $i$-ball in $\hat{M}$ in the same manner as for $M$ and the Kuiper completions of developing covers.

We will from now on be working on $\hat{M}$ only; however, all of the materials in this chapter will work for $M$ and the Kuiper completions of developing covers as well, and much of the materials in the remaining chapters will work also; however, we will not say explicitly as the readers can easily figure out these details.

An $n$-bihedron is bounded by two $(n-1)$-dimensional hemispheres; the corresponding subsets of $A$ are the sides of $A$ (see [12]).

**Definition 3.6.** — An $n$-ball $A$ of $\hat{M}$ is said to be an $n$-bihedron if $\text{dev}|A$ is a homeomorphism onto an $n$-bihedron. An $n$-ball $A$ of $\hat{M}$ is said to be an $n$-hemisphere if $\text{dev}|A$ is a homeomorphism onto an $n$-hemisphere in $S^n$.

A bihedron is said to be an $n$-crescent if one of its sides is a subset of $M_{h,\infty}$ and the other side is not. An $n$-hemisphere is said to be an $n$-crescent if a subset in the boundary corresponding to an $(n-1)$-hemisphere under $\text{dev}$ is a subset of $M_{h,\infty}$ and the boundary itself is not a subset of $M_{h,\infty}$.

Note that an $n$-crescent in $\hat{M}$ (or the Kuiper completions of developing covers) is defined in the same obvious manner.

To distinguish, a bihedral $n$-crescent is an $n$-crescent that is a bihedron, and a hemispheric $n$-crescent is an $n$-crescent that is otherwise.

In contrast to Definition 3.6, we define an $m$-bihedron for $1 \leq m \leq n-1$, to be only a tame topological $m$-ball whose image under $\text{dev}$ is an $m$-bihedron in a great $m$-sphere in $S^n$, and an $m$-hemisphere, $0 \leq m \leq n-1$, to be one whose image under $\text{dev}$ is an $m$-hemisphere. So, we do not necessarily have $A^o \subset M_{h}$ when $A$ is one of these.
Example 3.7. — Let us give two trivial examples of real projective $n$-manifolds to demonstrate $n$-crescents (see [10] for more $2$-dimensional examples).

Let $\mathbb{R}^n$ be an affine patch of $S^n$ with standard affine coordinates $x_1, x_2, \ldots, x_n$ and $O$ the origin. Consider $\mathbb{R}^n - \{O\}$ quotient out by the group $\langle g \rangle$ where $g : x \to 2x$ for $x \in \mathbb{R}^n - \{0\}$. Then the quotient is a real projective manifold diffeomorphic to $S^{n-1} \times S^1$. Denote the manifold by $N$, and we see that $N_b$ can be identified with $\mathbb{R}^n - \{O\}$. Thus, $N_b = \{O\}$ and $N_{b, \infty}$ is the union of $\{O\}$ and the boundary great sphere $S^{n-1}$ of $H$. Moreover, the closure of the set $R$ given by $x_1 + x_2 + \cdots + x_n > 0$ in $H$ is an $n$-bihedron and one of its side is included in $S^{n-1}$. Hence, $R$ is an $n$-crescent.

Let $H_1$ be the open half-space given by $x_1 > 0$, and let the line $x_2 = \cdots = x_n = 0$ (provided $n \geq 3$). Let $g_1$ be the real projective transformation given by $(x_1, x_2, \ldots, x_n) \mapsto (2x_1, x_2, \ldots, x_n)$ and $g_2$ that given by

$$(x_1, x_2, \ldots, x_n) \mapsto (x_1, 2x_2, \ldots, 2x_n).$$

Then the quotient manifold $L$ of $H_1 - l$ by the commutative group generated by $g_1$ and $g_2$ is diffeomorphic to $S^{n-2} \times S^1 \times S^1$, and we may identify its holonomy cover $L_b$ with $H_1 - l$ and $L_{h, \infty}$ with the closure $\text{Cl}(H_1)$ of $H_1$ in $S^n$. Clearly, $\text{Cl}(H_1)$ is an $n$-bihedron bounded by an $(n-1)$-sphere that is the closure of the hyperplane given by $x_1 = 0$ and an $(n-1)$-sphere in the boundary of the affine patch $\mathbb{R}^n$. Therefore, $L_{h, \infty}$ is the union of $H_1 \cap l$ and two $(n-1)$-hemispheres that form the boundary of $\text{Cl}(H_1)$. $\text{Cl}(H_1)$ is not an $n$-crescent since $\text{Cl}(H_1) \cap L_{h, \infty} \supset l \cap H_1 \neq \emptyset$. In fact, $\text{Cl}(H_1)$ includes no $n$-crescents.

Let $R$ be an $n$-crescent. If $R$ is an $n$-bihedron, then we define $\alpha_R$ to be the interior of the side of $R$ in $M_{h, \infty}$ and $\nu_R$ the other side. If $R$ is an $n$-hemisphere, then we define $\alpha_R$ to be the union of the interiors of all $(n-1)$-hemispheres in $\delta R \cap M_{h, \infty}$ and define $\nu_R$ the complement of $\alpha_R$ in $\delta R$. Clearly, $\nu_R$ is a tame topological $(n-1)$-ball.

Remark 3.8. — There is another definition of $n$-crescents due to the referee is as follows. An $n$-crescent set in $M_h$ is a closed subset $R$ of $M_h$ such that

- $\text{dev}$ restricted to $R$ is injective,
- $\text{dev}(\text{int}R)$ for the topological interior $\text{int}R$ of $R$ is an open $n$-hemisphere or an open $n$-bihedron,
- $\text{bd}R \cap M_h$ is not empty,
- $\text{dev}(\text{bd}R \cap M_h)$ is included in an $(n-1)$-hemisphere (equivalently, $\delta \text{dev}(R)$ includes an open $(n-1)$-hemisphere $\beta_R$ disjoint from $\text{dev}(R)$).

It is elementary to show the following: If $R$ is an $n$-crescent, then $R \cap M_h$ is an $n$-crescent set. Conversely, the closure of an $n$-crescent set in $M_h$ is obviously an $n$-crescent. Hence, there exists a canonical correspondence between $n$-crescent sets and $n$-crescents.

Finally, this definition shows some relationship between crescents and poque and coque defined by Benzécri [6].
Let us now discuss about how two convex sets may meet. Let $F_1$ and $F_2$ be two convex $i$-, $j$-balls in $M_h$ respectively. We say that $F_1$ and $F_2$ overlap if $F_1^o \cap F_2^o \neq \emptyset$. This is equivalent to $F_1 \cap F_2^2 \neq \emptyset$ or $F_1^2 \cap F_2^o \neq \emptyset$ when $F_1$ and $F_2$ are $n$-balls.

**Proposition 3.9.** If $F_1$ and $F_2$ overlap, then $\text{dev}(F_1 \cup F_2)$ is an imbedding onto $\text{dev}(F_1) \cup \text{dev}(F_2)$ and $\text{dev}(F_1 \cap F_2) \cap \text{dev}(F_2)$. Moreover, if $F_1$ and $F_2$ are $n$-balls, then $F_1 \cup F_2$ is an $n$-ball, and $F_1 \cap F_2$ is a convex $n$-ball.

**Proof.** The proof is a direct generalization of that of Theorem 1.7 of [10]. We see that it follows from Proposition 3.10 since $F_1$ and $F_2$ satisfy the premise as $\text{dev}(F_1)$ and $\text{dev}(F_2)$ are convex.

**Proposition 3.10.** Let $A$ be a $k$-ball in $M_h$ and $B$ an $l$-ball. Suppose that $A^o \cap B^o \neq \emptyset$, $\text{dev}(A) \cap \text{dev}(B)$ is a compact manifold in $S^n$ with interior equal to $\text{dev}(A^o) \cap \text{dev}(B^o)$ and $\text{dev}(A^o) \cap \text{dev}(B^o)$ is pathwise-connected. Then $\text{dev}(A \cup B)$ is a homeomorphism onto $\text{dev}(A) \cup \text{dev}(B)$.

**Proof.** This follows as in its affine version Lemma 6 in [16] but is rather elementary. First, we prove injectivity: Let $x \in A$, $y \in B$, and $z \in A^o \cap B^o$ with $\text{dev}(x) = \text{dev}(y)$. There is a path $\gamma$ in $\text{dev}(A) \cap \text{dev}(B)$ from $\text{dev}(z)$ to $\text{dev}(x)$ such that $\gamma|[0,1]$ maps into $\text{dev}(A)^o \cap \text{dev}(B)^o$. Since $\text{dev}(A)$ is an imbedding onto $\text{dev}(A)$, there is a lift $\gamma_A$ of $\gamma$ into $A^o$ from $z$ to $x$. Similarly, there is a lift $\gamma_B$ of $\gamma$ into $B^o$ from $z$ to $y$. Note that $\gamma_A|[0,1]$ agrees with $\gamma_B|[0,1]$ by the uniqueness of lifts of paths for immersions. Thus, $x = y$ since $M$ is a complete metric space.

By the injectivity, there is a well-defined inverse function $f$ to $\text{dev}(A \cup B)$; if restricted to $\text{dev}(A)$ equals the inverse map of $\text{dev}(A)$, and $f$ restricted to $\text{dev}(B)$ the inverse map of $\text{dev}(B)$. Since both inverse maps are continuous, and $\text{dev}(A)$ and $\text{dev}(B)$ are closed, $f$ is continuous. (See also [8].)

In the following, we describe a useful geometric situation modeled on “dipping a bread into a bowl of milk”. Let $D$ be a convex $n$-ball in $M_h$ such that $\delta D$ includes a tame subset $\alpha$ homeomorphic to an $(n-1)$-ball. We say that a convex $n$-ball $F$ is **dipped into** $(D, \alpha)$ if the following statements hold:

- $D$ and $F$ overlap.
- $F \cap \alpha$ is a convex $(n-1)$-ball $\beta$ with $\delta \beta \subset \delta F$ and $\beta^o \subset F^o$.
- $F^\circ - \beta$ has two convex components $O_1$ and $O_2$ such that $\text{Cl}(O_1) = O_1 \cup \beta = F - O_2$ and $\text{Cl}(O_2) = O_2 \cup \beta = F - O_1$.
- $F \cap D$ is equal to $\text{Cl}(O_1)$ or $\text{Cl}(O_2)$.

(The second item sometimes is crucial in this paper.) We say that $F$ is **dipped into** $(D, \alpha)$ **nicely** if the following statements hold:

- $F$ is dipped into $(D, \alpha)$.
- $F \cap D^o$ is identical with $O_1$ and $O_2$.
- $\delta(F \cap D) = \beta \cup \xi$ for a topological $(n-1)$-ball $\xi$, not necessarily convex or tame, in the topological boundary $\text{bd} F$ of $F$ in $M_h$ where $\beta \cap \xi = \delta \beta$.

As a consequence, we have $\delta \beta \subset \text{bd} F$. (As above this is a crucial point.) The nice dipping occurs when the bread does not touch the bowl.)
The direct generalization of Corollary 1.9 of [10] gives us:

**Corollary 3.11.** — Suppose that $F$ and $D$ overlap, and $F^o \cap (\delta D - \alpha^o) = \emptyset$. Assume the following two equivalent conditions:

- $F^o \cap \alpha \neq \emptyset$,  
- $F \notin D$.

Then $F$ is dipped into $(D, \alpha)$. If $F \cap (\delta D - \alpha^o) = \emptyset$ furthermore, then $F$ is dipped into $(D, \alpha)$ nicely.

**Example 3.12.** — In Example 3.7, choose a compact convex ball $B$ in $\mathbb{R}^n - \{O\} = N_h$ intersecting $R$ in its interior but not included in $R$. Then $B$ dips into $(R, P)$ nicely where $P$ is the closure of the plane given by $x_1 + \cdots + x_n = 0$. Also let $S$ be the closure of the half plane given by $x_1 > 0$. Then $S$ dips into $(R, P)$ but not nicely.

Consider the closure of the set in $N_h$ given by $0 < x_1 < 1$ and that of the set $0 < x_2 < 1$. Then these two sets do not dip into each other for any choice of $(n - 1)$-balls in their respective boundaries to play the role of $\alpha$.

Since $\text{dev}$ restricted to small open sets are charts, and the boundary of $M_h$ is convex, each point $x$ of $M_h$ has a compact ball-neighborhood $B(x)$ so that $\text{dev}|B(x)$ is an imbedding onto a compact convex ball in $S^n$ (see Section 1.11 of [10]). $\text{dev}(B(x))$ can be assumed to be a $d$-ball with center $\text{dev}(x)$ and radius $\epsilon > 0$ intersected with an $n$-hemisphere $H$ so that $\delta M_h \cap B(x)$ corresponds to $\delta H \cap \text{dev}(B(x))$. Of course, $\delta M_h \cap B(x)$ or $\delta H \cap \text{dev}(B(x))$ may be empty. We say that such $B(x)$ is an $\epsilon$-tiny ball of $x$ and $\epsilon$ the $d$-radius of $B(x)$.

Note that for an $\epsilon$-tiny ball $B(x)$, $\delta M_h \cap B(x)$ is a compact convex $(n - 1)$-ball or empty, and the topological boundary $\text{bd}B(x)$ equals the closure of $\delta B(x)$ removed with this set.

**Lemma 3.13.** — If $B(x)$ and an $n$-crescent $R$ overlap, then either $B(x)$ is a subset of $R$ or $B(x)$ is dipped into $(R, \nu_R)$ nicely.

**Proof.** — Since $\text{Cl}(\alpha_R) \subset M_h, \infty$ and $B(x) \subset M_h$, Corollary 3.11 implies the conclusion.
As promised, we will reproduce two propositions on the sequences of convex \(n\)-balls that “converge” to a convex ball in the Kuiper completions from the Appendix of [10].

Recall that \(\mu\) denote the Riemannian metric on \(M_h\) induced from that of \(\mathbb{S}^n\) by \(\text{dev}\).

**Proposition 3.14.** — Let \(\{D_i\}\) be a sequence of convex \(n\)-balls in \(M_h\). Let \(x \in M_h\), and \(B(x)\) a tiny ball of \(x\). Suppose that the following properties hold:

1. \(\delta D_i\) includes an \((n-1)\)-ball \(v_i\).
2. \(B(x)\) overlaps with \(D_i\) and does not meet \(\delta D_i - \text{Cl}(v_i)\).
3. A sequence \(\{x_i\}\) converges to \(x\) where \(x_i \in v_i\) for each \(i\).
4. The sequence \(\{n_i\}\) converges where \(n_i\) is the outer-normal \(d\)-unit vector to \(v_i\) at \(x_i\) with respect to \(\mu\) for each \(i\).

Then there exist a positive integer \(N\) and a convex open disk \(\mathcal{P}\) in \(B(x)\) such that \(\mathcal{P} \subset D_i\) whenever \(i > N\).

**Proof.** — The appendix of [10] has the proof in dimension 2, which easily generalizes to the dimension \(n\). We follow this proof. Let \(c\) be a positive real number so that \(d(x, bdB(x)) > c\). Let \(s_i\) be the inward maximal segment in \(D_i \cap B(x)\) with an endpoint \(x_i\) in \(v_i\). Choosing \(N_1\) so that for \(i > N_1\), \(d(x_i, x) < c/2\). Then the \(d\)-length of \(s_i\) is greater than \(c/2\) for \(i > N_1\). Choose a point \(y_i\) on \(s_i\) of distance \(c/4\) from \(x_i\). Then we have \(d(y_i, bdB(x)) > c/4\).

For each \(i\), it is easy to see that \(D_i \cap B(x)\) includes the ball \(B_{c/4}(y_i)\) of \(d\)-radius \(c/2\) with center \(y_i\). As \(n_i\) converges to a \(d\)-unit vector at \(x\), the sequence of points \(y_i\) converges to a point \(y\) of \(B(x)\). Choosing \(N, N > N_1\), to be so that for \(i > N\) \(d(y_i, y) < c/8\), we obtain that \(B_{c/4}(y_i) \supset B_{c/8}(y)\) for \(i > N\). Letting \(\mathcal{P}\) equal \(B_{c/8}(y)\) completes the proof. \(\square\)

We say that a compact subset \(D_\infty\) of \(\mathbb{S}^n\) is the resulting set of a sequence \(\{D_i\}\) of compact subsets of \(M_h\) if \(\text{dev}(D_i)\) converges to \(D_\infty\). Let \(\{D_i\}\) and \(\{B_i\}\) be sequences of convex \(n\)-balls with resulting sets \(D_\infty\) and \(B_\infty\) respectively; let \(\{K_i\}\) be a sequence of compact subsets with the resulting set \(K_\infty\). We say that \(\{D_i\}\) subjugates \(\{K_i\}\) if \(D_i \supset K_i\) for each \(i\) and that \(\{B_i\}\) dominates \(\{D_i\}\) if \(B_i \supset D_i\) for each \(i\) and \(B_\infty\) includes \(D_\infty\). Moreover, we say that \(\{K_i\}\) is ideal if there is a positive integer \(N\) for every compact subset \(F\) of \(M_h\) such that \(F \cap K_i = \emptyset\) whenever \(i > N\). In particular, if \(K_i\) is a subset of \(M_{h,\infty}\) for each \(i\), then \(\{K_i\}\) is an ideal subjugated sequence.

**Proposition 3.15.** — Suppose that \(\{D_i\}\) is a sequence of \(n\)-balls including a common open ball \(\mathcal{P}\), \(\{B_i\}\) is another sequence of \(n\)-balls, and \(\{K_i\}\) a sequence of subsets of \(M_h\). Assume that \(\{D_i\}\) subjugates \(\{K_i\}\) and that \(\{B_i\}\) dominates \(\{D_i\}\). Then \(M_h\) includes two convex \(n\)-balls \(D^u\) and \(B^u\) and a compact subset \(K^u\) with the following properties:

1. \(D^u \supset \mathcal{P}\), and \(\text{dev}(D^u) = D_\infty\).
2. \(B^u \supset D^u\), and \(\text{dev}(B^u) = B_\infty\).
3. \(D^u \supset K^u\), and \(\text{dev}(K^u) = K_\infty\).
4. If \(\{K_i\}\) is ideal, then \(K^u \subset M_{h,\infty}\).
Proof. — The proof is identical with that of Theorem 4 in the Appendix of [10]:

(1) Since \( \text{dev}(D_i) \) includes \( \text{dev}(P) \) for each \( i \), we have \( D_\infty \supset \text{dev}(P) \); hence, \( D_\infty \) is a convex \( n \)-ball. Since Proposition 2.10 implies

\[
\bigcup_{i=1}^\infty \text{dev}(D_i)^o \supset D_\infty^o,
\]

by Proposition 3.10 \( \text{dev}|\bigcup_{i=1}^\infty D_i^o \) is an imbedding onto \( \bigcup_{i=1}^\infty \text{dev}(D_i)^o \). Thus, \( \bigcup_{i=1}^\infty D_i^o \) includes a convex disk \( D_{sp} \) such that \( \text{dev}|D_{sp} \) is an imbedding onto \( D_\infty^o \). If we let \( D^u = \text{Cl}(D_{sp}) \), then (1) follows.

(2) Let \( P' \) be a compact convex \( n \)-ball in \( P^o \); let \( P'' \) be its interior \( (P')^o \). Noting that \( B_\infty \supset \text{dev}(P) \), a point \( x \) of \( \text{dev}(P'') \) satisfies \( d(x, \delta B_\infty) > \epsilon \) for a small positive constant \( \epsilon \). Lemma 2.11 easily shows that there is a positive integer \( N \) such that

\[
\text{dev}(B_i) \supset \text{dev}(P'') \quad \text{whenever} \quad i > N.
\]

Since \( \text{dev}|B_i \cup D_i \) is an imbedding onto \( \text{dev}(B_i) \cup \text{dev}(D_i) \) by Proposition 3.9 and \( D_i \supset P \), it follows that \( B_i \supset P^u \) whenever \( i > N \). (2) follows from (1).

(3) Since \( K_i \subset D_i \) for each \( i \), we have \( K_\infty \subset D_\infty \). Let \( K'' = (\text{dev}|D^u)^{-1}(K_\infty) \).

(3) follows.

(4) We show that \( K'' \subset M_{h, \infty} \). To the contrary, suppose that \( K'' \cap M_h \) contains a point \( x \). Suppose further that \( x \in M_h^o \); thus, there is a tiny ball \( B(x) \) satisfying \( x \in B(x)^o \) and such that \( \text{dev}(B(x))^o \cap D_\infty^o \) is star-shaped from a point \( y \) of \( \text{dev}(P) \). (A star-shaped subset of \( S^n \) from a point is a subset such that each of its elements can be connected by a simply convex segment in it from the point.) We obtain by Proposition 3.10 that

\[
\text{dev}|D_i \cup B(x) \cup D^u
\]

is an imbedding onto

\[
\text{dev}(D_i) \cup \text{dev}(B(x)) \cup D_\infty
\]

for each \( i \).

Since \( \{ \text{dev}(K_i) \} \) converges to \( K_\infty \) and \( \text{dev}(B(x))^o \) is an open neighborhood of \( \text{dev}(x) \), there is a positive integer \( N \) such that

\[
\text{dev}(K_i) \cap \text{dev}(B(x))^o \neq \emptyset \quad \text{whenever} \quad i > N.
\]

Let \( i \) be an integer greater than \( N \). The open disk \( B(x)^o \) includes a non-empty subset \( \delta_i \) defined by

\[
\delta_i = (\text{dev}|B(x)^o)^{-1}(\text{dev}(K_i) \cap \text{dev}(B(x))^o).
\]

By the conclusion of the second paragraph above, \( \delta_i \) is a subset of \( K_i \). Since we have \( \delta_i \subset B(x) \) whenever \( i > N \), this contradicts the premise on \( \{ K_i \} \).

Finally, suppose that \( x \in \delta M_h \). Let us extend \( M_h \) by attaching a small open \( n \)-ball in \( S^n \) around \( x \) by a projective map. The resulting projective surface still has convex boundary. Now the previous argument applies and yields a contradiction again. \( \square \)

As an immediate application, we have
Corollary 3.16. — Suppose that $M$ is not projectively diffeomorphic to an open $n$-bihedron or $n$-hemisphere. Let $R_i$ be a sequence of $n$-crecents such that a sequence of points $x_i \in \nu_{R_i}$ converges to a point $x$ of $M_h$. Then $M_h$ includes a crescent $R$ containing $x$ so that $\text{dev}(R_i)$ converges to $\text{dev}(R)$ for a subsequence $R_{i_j}$ of $R_i$ and $R$ and $R_{i_j}$ include a common open ball $\mathcal{P}$ for $j$ sufficiently large. Finally if $R_i$ are $n$-hemispheres, then so is $R$. If $R_i$ are $n$-bihedrons, then $R$ is either an $n$-hemisphere or an $n$-bihedron.

Proof. — Assume without loss of generality that $x_i \in B(x)$ and that the sequence of $d$-unit outer normal vectors $n_i$ at $x_i$ converges to one at $x$. Then by Proposition 3.14, there exists a common ball $\mathcal{P}$ in $R_i \cap B(x)$ for $i$ sufficiently large.

Note that $\text{Cl}(\alpha_i) \subset R_i$. By choosing a subsequence, we may assume that $\text{dev}(\text{Cl}(\alpha_i))$ converges to a compact set $\alpha$ so that $\text{Cl}(\alpha_i)$ forms a subjugated sequence of $R_i$. Moreover $\text{Cl}(\alpha_i)$ forms an ideal one since $\text{Cl}(\alpha_i)$ never meets any compact subset of $M_h$.

By Proposition 3.15, there exists a convex $n$-ball $R$ in $M_h$ so that a subsequence of $\text{dev}(R_i)$ converges to $\text{dev}(R)$. Since each $\text{Cl}(\alpha_i)$ includes an $(n-1)$-hemisphere, so does $\alpha$ by Proposition 2.8. Hence, $\text{dev}(R)$ is an $n$-hemisphere or an $n$-bihedron by Lemma 2.5. Furthermore, a subset $\alpha''$ of $R$ which maps to $\alpha$ includes an $(n-1)$-hemisphere. If $\delta R$ is a subset of $M_{h,\infty}$, then $M_h$ is diffeomorphic to an open $n$-bihedron or $n$-hemisphere by the following lemma 3.17. Thus, $R$ is an $n$-crescent as $\alpha''$ is a subset of $M_{h,\infty}$ by Proposition 3.15.

Since $R$ includes $\mathcal{P}$, $R$ overlaps $B(x)$. Hence, $\text{dev}|R \cup B(x)$ is a homeomorphism onto $\text{dev}(R) \cup \text{dev}(B(x))$. Since $\text{dev}(R)$ contains $\text{dev}(x)$, we have that $x \in R$.

The two last statements follow from Proposition 2.8.

Lemma 3.17. — Suppose that $M_h$ includes an $n$-ball $B$ with $\delta B \subset M_{h,\infty}$. Then $M_h$ equals $B^\circ$.

Remark 3.18. — We can relax the condition $x_i \in \nu_{R_i}$ to $x_i \in R_i$ in Corollary 3.16. The proof requires us to choose a smaller crescent $S_i$ in $R_i$ so that $x_i \in \nu_{S_i}$ and $\alpha_{S_i} \subset \alpha_{R_i}$. The rest of the straightforward proof is left to the reader.
PART II

\( (n - 1) \)-CONVEXITY AND DECOMPOSITION
CHAPTER 4

(n − 1)-CONVEXITY AND n-CRESCECTS

In this chapter, we introduce m-convexity. Then we state Theorem 4.6 central to this chapter, which relates the failure of (n − 1)-convexity with an existence of n-crescents, or half-spaces. The proof of theorem is similar to what is in Section 5 in [10]. Let M be a real projective n-manifold with empty or totally geodesic boundary; let $M_h$ be the holonomy cover and $M_h$ the Kuiper completion of $M_h$. An m-simplex $T$ in $M_h$ is a tame subset of $M_h$ such that $\text{dev}(T)$ is an imbedding onto an affine $m$-simplex in an affine patch in $S^n$. If $M$ is compact but not (n − 1)-convex, then we can show that there exists an $n$-simplex $T$ in $M_h$ with sides $F_1, \ldots, F_m$ so that $T \cap M_{h,\infty}$ is a nonempty subset of the interior of $F_1$. We first choose a sequence of points $q_i$ of $F_1$ converging to a point $x$ in $F_1 \cap M_{h,\infty}$. Then we pull back $q_i$ to points $p_i$ in the closure of a fundamental domain by a deck transformation $\vartheta_i^{-1}$. Then analogously to [10], we show that $T_i = \vartheta_i^{-1}(T)$ “converges to” a nondegenerate convex $n$-ball. Showing that $\text{dev}(T_i)$ converges to an $n$-bihedron or an $n$-hemisphere is more complicated than in [10]. The idea of the proof is to show that the sequence of the images under $\vartheta_i$ of the $\epsilon$-(n − 1)-balls in $\vartheta_i^{-1}(F_1)$ with center $p_i$ often have to degenerate to a point when $x$ is chosen specially. So when pulled back by $\vartheta_i^{-1}$, the balls become standard ones again, and $F_1$ must blow up to be an (n − 1)-hemisphere under $\vartheta_i^{-1}$.

**Definition 4.1.** — We say that $M$ is m-convex, $0 < m < n$, if the following holds. If $T \subset M_h$ is an $(m + 1)$-simplex with sides $F_1, F_2, \ldots, F_{m+2}$ such that $T \cap M_{h,\infty}$ does not meet $M_{h,\infty}$, then $T$ is a subset of $M_h$.

**Proposition 4.2.** — Let $T$ be an affine $(m + 1)$-simplex in an affine space with sides $F_1, F_2, \ldots, F_{m+2}$. The following are equivalent:

(a) $M$ is m-convex.
(b) Any real projective immersion $f$ from $T^o \cup F_2 \cup \cdots \cup F_{m+2}$ to $M$ extends to one from $T$.
(c) Every cover of $M$ is m-convex.

**Proof.** — The proof of the equivalence of (a) and (b) is the same as the affine version Lemma 1 in [16]: Suppose that $M$ is not m-convex, and let $p : \tilde{M} \to M$ denote the
universal covering map. Then there exists a \(d\)-simplex \(T\) in \(M\) such that \(T \cap M_\infty = F'_i \cap M_\infty \neq \emptyset\) for a side \(F'_1\) of \(T\). Since \(T\) is a \(d\)-simplex, \(\text{dev}(T)\) is an imbedding onto \(\text{dev}(T)\), and \(\text{dev}(T)\) is a \(d\)-simplex in an affine patch of \(\mathbb{RP}^m\). Let \(f\) be the map \((\text{dev} \circ \text{dev}(T))^{-1}\) restricted to \(\text{dev}(T) \cup \text{dev}(F_2) \cup \cdots \cup \text{dev}(F_{m+2})\). \(f\) is a projective immersion to \(\hat{M}\). It is easy to see that \(f\) does not extend to all of \(\text{dev}(T)\). Hence, \(p \circ f\) is an affine immersion which does not extend to \(\text{dev}(T)\).

Suppose that \(M\) is \(m\)-convex. Let \(\text{dev} : M \to \mathbb{RP}^m\) be the developing map. Let \(f : T^0 \cup F_2 \cup \cdots \cup F_{m+2}\) be a projective immersion into \(M\), and let \(\hat{f}\) be the lift of \(f\) to \(\hat{M}\). Then \(\text{dev} \circ \hat{f}\) is also a real projective immersion from \(T^0 \cup F_2 \cup \cdots \cup F_{m+2}\) into \(\mathbb{RP}^m\). Since the rank of the map \(\text{dev} \circ \hat{f}\) is maximal, the map extends to a global real projective transformation \(\phi\) on \(\mathbb{RP}^m\), and hence \(\text{dev} \circ \hat{f}\) is an imbedding. Since \(\text{dev} \hat{f}(T^0)\) is an imbedding onto an open \(m\)-simplex \(\text{dev} \circ \hat{f}(T^0)\) in \(\mathbb{RP}^m\), and \(\hat{f}(T^0)\) is a convex subset of \(\hat{M}\), it follows that the closure \(\hat{T}\) of \(\hat{f}(T^0)\) is a tame subset of \(\hat{M}\) so that \(\text{dev} \hat{T}\) is an imbedding onto \(\text{Cl}(\hat{f}(T^0))\).

Since \(T^i\) is an \((m+1)\)-simplex with sides \(\hat{f}(F_2), \ldots, \hat{f}(F_{m+2})\), and a remaining side \(F'_1\). Since \(T^0\) and \(\hat{f}(F_2), \ldots, \hat{f}(F_{m+2})\) are subsets of \(\hat{M}\), and \(M\) is \(m\)-convex, we have \(T^i \subset \hat{M}\). Therefore the affine embedding \(\hat{f} : T \to T^i\) given as \((\text{dev} \hat{T})^{-1} \circ \phi\) extends \(\hat{f}\) and \(p \circ f\) extends \(f\).

The equivalence of (b) and (c) follows from the fact that a real projective map to \(M\) always lifts to its cover. \(\square\)

**Proposition 4.3.** — \(M\) is not \(m\)-convex if and only if there exists an \((m+1)\)-simplex with a side \(F_1\) such that \(T \cap M_{h,\infty} = F'_i \cap M_{h,\infty} \neq \emptyset\).

**Proof.** — This elementary proof is same as Lemma 3 in [16]. Suppose that every \((m+1)\)-simplex \(T\) has the property that \(T\) do not meet \(M_{h,\infty}\) or \(T \cap M_{h,\infty}\) is a subset of the union of two or more sides but not less than two sides or if \(T \cap M_{h,\infty}\) is a subset of a side \(F_i\), then \(F \cap M_{h,\infty}\) is not a subset of \(F^0\). Then one sees easily that the definition for \(m\)-convexity is satisfied by \(M\).

Conversely, if \(M\) is \(m\)-convex, and \(T\) is an \((m+1)\)-simplex with sides \(F_1, \ldots, F_{m+2}\) such that \(T^0 \cup F_2 \cup \cdots \cup F_{m+2} \subset M_h\), then \(T \subset \hat{M}\). Consequently, there is no \((m+1)\)-simplex \(T\) with \(T \cap M_{h,\infty} = F'_i \cap M_{h,\infty} \neq \emptyset\). \(\square\)

**Remark 4.4.** — It is easy to see that \(i\)-convexity implies \(j\)-convexity whenever \(i \leq j < n\). (See Remark 2 in [16]. The proof is the same.)

**Theorem 4.5.** — The following are equivalent: \(M\) is 1-convex; \(M\) is convex; \(M\) is real projectively isomorphic to a quotient of a convex domain in \(S^n\).

The proof is similar to Lemma 8 in [16]. Since there are minor differences between affine and real projective manifolds, we will prove this theorem in Appendix A.

Let us give examples of real projective \(n\)-manifolds one of which is not \((n-1)\)-convex and the other \((n-1)\)-convex.

As in Figure 4.1, \(\mathbb{R}^3\) removed with a complete affine line or a closed wedge, i.e., a set defined by the intersection of two half-spaces with non-parallel boundary planes is obviously 2-convex. But \(\mathbb{R}^3\) removed with a discrete set of points or a convex
cone defined as the intersection of three half-spaces with boundary planes in general position is not 2-convex.

We recall Example 3.7. Let $\mathbb{R}^n$ be an affine patch of $S^n$ with standard affine coordinates $x_1, x_2, \ldots, x_n$ and $O$ the origin. Consider $\mathbb{R}^n - \{O\}$ quotient out by the group $\langle g \rangle$ where $g : x \to 2x$ for $x \in \mathbb{R}^n - \{0\}$. Then the quotient is a real projective manifold diffeomorphic to $S^{n-1} \times S^1$. We denoted the manifold by $N$, and we see that $N_h$ can be identified with $\mathbb{R}^n - \{0\}$. Thus, $N_h$ equals the closure of $\mathbb{R}^n$ in $S^n$; that is, $N_h$ equals an $n$-hemisphere $H$, and $N_{h, \infty}$ is the union of $\{O\}$ and the boundary great sphere $S^{n-1}$ of $H$. Consider an $n$-simplex $T$ in $\mathbb{R}^n$ given by $x_i \leq 1$ for every $i$ and $x_1 + x_2 + \cdots + x_n \geq 0$. Then the side of $T$ corresponding to $x_1 + x_2 + \cdots + x_n = 0$ contains the ideal point $O$ in its interior. Therefore, $N$ is not $(n-1)$-convex. Moreover, the closure of the set given by $x_1 + x_2 + \cdots + x_n > 0$ in $M_h = H$ is an $n$-bihedron and one of its side is included in $S^{n-1}$. Hence, it is an $n$-crescent. (It will aid understanding to apply each course of the proof of Theorem 4.6 to this example.)

Let $H_1$ be the open half-space given by $x_1 > 0$, and $l$ the line $x_2 = \cdots = x_n = 0$. Let $g_1$ be the real projective transformation given by $(x_1, x_2, \ldots, x_n) \mapsto (2x_1, x_2, \ldots, x_n)$ and $g_2$ that given by $(x_1, x_2, \ldots, x_n) \mapsto (x_1, 2x_2, \ldots, 2x_n)$. Then the quotient manifold $L$ of $H_1 - l$ by the commutative group generated by $g_1$ and $g_2$ is diffeomorphic to $S^{n-2} \times S^1 \times S^1$, and we may identify $L_h$ with $H_1 - l$ and $L_h$ with the closure $\text{Cl}(H_1)$ of $H_1$ in $S^n$. Clearly, $\text{Cl}(H_1)$ is an $n$-bihedron bounded by an $(n-1)$-hemisphere that is the closure of the hyperplane given by $x_1 = 0$ and an $(n-1)$-hemisphere in the boundary of the affine patch $\mathbb{R}^n$. Therefore, $L_{h, \infty}$ is the union of $H_1 \cap l$ and two $(n-1)$-hemispheres that form the boundary of $\text{Cl}(H_1)$. The intersection of an $n$-simplex $T$ in $S^n$ with the boundary $(n-1)$-hemispheres or $l$ is not a subset of the interior of a side of $T$. It follows from this that $L$ is $(n-1)$-convex.

The main purpose of this chapter is to prove the following principal theorem:

**Theorem 4.6.** — Suppose that a compact real projective manifold $M$ with empty or totally geodesic boundary is not $(n-1)$-convex. Then the completion $M_h$ of the holonomy cover $M_h$ includes an $n$-crescent.
We may actually replace the word “totally geodesic boundary” with “convex boundary” and the proof is same step by step. However, we need this result at only one point of the paper so we do not state it.

We can also show that the completion $\hat{M}$ of the universal cover $\hat{M}$ also includes an $n$-crescent. The proof is identical with $M$ replacing $\hat{M}$. Another way to do this is of course as follows: once we obtain an $n$-crescent in $\hat{M}$ we may lift it to one in $M$ (see Proposition 8.13).

Remark 4.7. — As $M$ is not $(n-1)$-convex, we may assume that $\hat{M}$ or $M_h$ is not projectively diffeomorphic to an open $n$-bihedron or an open $n$-hemisphere: If otherwise, $\hat{M}$ is convex and hence $(n-1)$-convex. We will need this weaker but important hypothesis later.

A point $x$ of a convex subset $A$ of $\mathbb{S}^n$ is said to be exposed if there exists a supporting great $(n-1)$-sphere $H$ at $x$ such that $H \cap A = \{x\}$ (see Chapter 2 and Berger [7, p. 361]).

To prove Theorem 4.6, we follow Section 5 of [10]: Since $M$ is not $(n-1)$-convex, $M_h$ includes an $n$-simplex $T$ with a side $F_1$ such that $T \cap M_{h,\infty} = F_1 \cap M_{h,\infty} \neq \emptyset$ by Proposition 4.3, where $\text{dev}(T : T \to \text{dev}(T))$ is an imbedding onto the $n$-simplex $\text{dev}(T)$. Let $K$ be the convex hull of $\text{dev}(F_1 \cap M_{h,\infty})$ in $\text{dev}(F_1)^c$, which is simply convex as $\text{dev}(F_1)$ is simply convex.

As $K$ is simply convex, we see that $K$ can be considered as a bounded convex subset of an affine patch, i.e., an open $n$-hemisphere. We see easily that $K$ has an exposed point in the affine sense in the open hemisphere, which is easily seen to be an exposed point in our sense as a hyperplane in the affine patch is the intersection of a hypersphere with the affine patch.

Let $x'$ be an exposed point of $K$. Then $x' \in \text{dev}(F_1 \cap M_{h,\infty})$, and there exists a line $s'$ in the complement of $K$ in $\text{dev}(F_1)^c$ ending at $x'$. Let $x$ and $s$ be the inverse images of $x'$ and $s'$ in $F_1^c$ respectively.

Let $F_i$ for $i = 2, \ldots, n+1$ denote the sides of $T$ other than $F_1$. Let $v_i$ for each $i$, $i = 1, \ldots, n+1$, denote the vertex of $T$ opposite to $F_i$. Let us choose a monotone sequence of points $q_i$ on $s$ converging to $x$ with respect to $d$.

Choose a fundamental domain $F$ in $M_h$ such that for every point $t$ of $F$, there exists a $2\epsilon$-tiny ball of $t$ in $M_h$ for a positive constant $\epsilon$ independent of $t$. We assume $\epsilon \leq \pi/8$ for convenience. Let us denote by $F_2$ the closure of the $2\epsilon$-neighborhood of $F$, and $F_1$ that of the $\epsilon$-neighborhood of $F$ so that $F_1$ and $F_2$ are compact subsets of $M_h$.

For each natural index $i$, we choose a deck transformation $\vartheta_i$ and a point $p_i$ of $F$ so that $\vartheta_i(p_i) = q_i$. We let $v_{ji}, F_{ji}$, and $T_i$, $i = 1, 2, \ldots, j = 1, \ldots, n+1$, denote the images under $\vartheta_i^{-1}$ of $v_j, F_j$, and $T$ respectively. Let $n_i$ denote the outer-normal vector to $F_{ji}$ at $p_i$ with respect to the spherical Riemannian metric $\mu$ of $M_h$.

We choose subsequences so that each sequence consisting of $\text{dev}(v_{ji}), \text{dev}(F_{ji}), \text{dev}(T_i), n_i, \text{and } p_i$ converge geometrically with respect to $d$ for each $j, j = 1, \ldots, n+1$ respectively. Since $p_i$ belongs to the fundamental domain $F$ for each $i$, the limit $p$ of the sequence...
of \( p_i \) belongs to \( \text{Cl}(F) \). We choose an \( \epsilon \)-tiny ball \( B(p) \) of \( p \). We may assume without loss of generality that \( p_i \) belongs to the interior \( \text{int}B(p) \) of \( B(p) \). Since the action of the deck transformation group is properly discontinuous on \( M_h \) and \( F_{j,i} = \vartheta_i^{-1}(F_j) \) for a compact subset \( F_j \) of \( M_h \), there exists a natural number \( N \) such that

\[
F_{2i} \cap F_{j,i} = \emptyset \text{ for each } j, i, j > 1, i > N; \tag{4.1}
\]

so \( B(p) \cap F_{j,i} = \emptyset \) for \( j > 1 \). (This corresponds to Lemma 5.4 in [10].) Hence, \( B(p) \subset T_i \) or \( B(p) \) dips into \( (T_i, F_{1,i}) \) for each \( i, i > N \), by Corollary 3.11.

\[\text{Figure 4.2. The pull-back process}\]

By Proposition 3.14, there exists an integer \( N_1, N_1 > N \), such that \( T_i \) includes a common open ball for \( i > N_1 \). Let \( T_\infty \) be the limit of \( \text{dev}(T_i) \). Since \( \text{dev}(T_i) \) includes a common ball for \( i > N_1 \), Proposition 2.8 shows that \( T_\infty \) is a closed convex \( n \)-ball in \( S^n \).

Let \( F_{j,i} \) denote the limit of \( \text{dev}(F_{j,i}) \). Then \( \bigcup_{j=1}^{n+1} F_{j,i} \) is the boundary \( \delta T_\infty \) by Proposition 2.10.

Proposition 3.15 implies that \( M_h \) includes a convex \( n \)-ball \( T^n \) and convex sets \( F_j^n \) such that \( \text{dev} \) restricted to them are imbeddings onto \( T_\infty \) and \( F_{j,\infty} \) respectively. We have \( F_{j}^n \subset M_{h,\infty} \) for \( j \geq 2 \) from the same proposition since \( F_{j,i} \) is ideal.

As we shall prove below that \( F_{1,\infty} \) is an \( (n - 1) \)-hemisphere, \( T_\infty \) is a compact convex \( n \)-ball in \( S^n \) including the \( (n - 1) \)-hemisphere \( F_{1,\infty} \) in its boundary \( \delta T_\infty \). By Lemma 2.5, \( T_\infty \) is an \( n \)-bihedron or an \( n \)-hemisphere. As \( \bigcup_{j \geq 2} F_j^n \) is a subset of \( M_{h,\infty} \), if \( F_1^n \subset M_{h,\infty} \), then \( M_h = T^n \) and \( M_h \) equals the interior of \( T^n \) by Lemma 3.17. \( M_h \) is not projectively diffeomorphic to an open \( n \)-bihedron or an open \( n \)-hemisphere (see Remark 4.7): \( F_1^n \) is not a subset of \( M_{h,\infty} \). Since \( T^n \) is bounded by \( F_1^n \) and

\[
F_2^n \cup \cdots \cup F_{n+1}^n \subset M_{h,\infty},
\]
it follows that $T$ is an $n$-crescent. This completes the proof of Theorem 4.6.

We will now show that $F^o_i$ is an $(n - 1)$-dimensional hemisphere. This corresponds to Lemma 5.5 of [10] showing that one of the sides is a segment of $d$-length $\pi$. The following process may require us to choose further subsequences of $T_i$. However, since $\text{dev}(F_{1,i})$ is assumed to converge to $F_{1,\infty}$, we see that we need to only show that a subsequence of $\text{dev}(F_{1,i})$ converges to an $(n - 1)$-hemisphere.

The sequence $\text{dev}(q_i) = h(\vartheta_i)\text{dev}(p_i)$ converges to $x'$. Since $p_i$ belongs to $F$, $M_h$ includes an $\epsilon$-tiny ball $B(p_i)$ and a $2\epsilon$-tiny ball $B'(p_i)$ of $p_i$. Let $W(p_i) = F_{1,i} \cap B(p_i)$ and $W'(p_i) = F_{1,i} \cap B'(p_i)$. We assume that $i > N_1$ from now on.

We now show that $W(p_i)$ and $W'(p_i)$ are “whole” $(n - 1)$-balls of $d$-radius $\epsilon$ and $2\epsilon$, i.e., they map to such balls in $S^n$ under $\text{dev}$ respectively, or they are not “cut off” by the boundary $\delta F_{1,i}$.

If $p_i \in \delta M_h$, then the component $L$ of $F_{1,i} \cap M_h$ containing $p_i$ is a subset of $\delta M_h$ by Lemma 3.1. This component is a submanifold of $\delta M$ with boundary $\delta F_{1,i}$. Since $\delta F_{1,i}$ is a subset of $\bigcup_{j \geq 2} F_{j,i}$, and $B(p_i)$ is disjoint from it by equation 4.1, $\delta M_h \cap B(p_i)$ is a subset of $L$. Thus, $W(p_i)$ equals the convex $(n - 1)$-ball $\delta M_h \cap B(p_i)$ with boundary in $\partial B(p_i)$ and is a $d$-ball in $F_{1,i}$ of dimension $(n - 1)$ of $d$-radius $\epsilon$ and center $p_i$, and certainly maps to an $(n - 1)$-ball of $d$-radius $\epsilon$ with center $\text{dev}(p_i)$.

If $p_i \in M_h^0$, then since $F_{1,i}$ passes through $p_i$ and $F_{j,i} \cap B(p_i) = \emptyset$ for $j \geq 2$, it follows that $B(p_i)$ dips into $(T_i,F_{1,i})$ nicely by Corollary 3.11. Thus $W(p_i)$ is an $(n - 1)$-ball with boundary in $\partial B(p_i)$, and an $\epsilon$-$d$-ball in $F_{1,i}$ of dimension $(n - 1)$ with center $p_i$.

Similar reasoning shows that $W'(p_i)$ is a $2\epsilon$-$d$-ball in $F_{1,i}$ of dimension $(n - 1)$ with center $p_i$ for each $i$.

Since $\vartheta_i(W(p_i)) \subseteq F_1$, and $\text{dev}(F_1)$ is a compact set, we may assume without loss of generality by choosing subsequences of $\vartheta_i$ that the sequence of the subsets $\text{dev}(\vartheta_i(W(p_i)))$ of $\text{dev}(F_1)$, equal to $h(\vartheta_i)(\text{dev}(W(p_i)))$, converges to a set $W_{1,\infty}$ containing $x'$ in $\text{dev}(F_1)$. Since $\text{dev}|T^u$ is an imbedding onto $T_\infty$, there exists a compact tame subset $W_{1,\infty}$ in $F_1$ such that $\text{dev}$ restricted to $W_{1,\infty}$ is an imbedding onto $W_{1,\infty}$. $\vartheta_i(W(p_i))$ is a subjugated sequence of the sequence of convex $n$-balls that equal $T$ always. Since $W(p_i)$ is a subset of a compact set $F_\infty$, it follows that $\vartheta_i(W(p_i))$ is ideal, and $W_{1,\infty} \subseteq M_{h,\infty}$ by Proposition 3.15. We obtain $W^u \subseteq F_1 \cap M_{h,\infty}$.

For the proof of the next proposition, the fact that $x'$ is exposed will play a role:

**Proposition 4.8.** $W_{1,\infty}$ consists of the single point $x'$.

Suppose not. Then as $\text{dev}(\vartheta_i(W(p_i)))$ does not converge to a point, there has to be a sequence $\{\text{dev}(\vartheta_i(z_i))\}$, $z_i \in W(p_i)$, converging to a point $x'$ distinct from the limit $x'$ of $\{\text{dev}(q_i)\}$. Since we have $\text{dev}(q_i) = \text{dev}(\vartheta_i(p_i))$, we choose $s_i$ to be the $d$-diameter of $W(p_i)$ containing $z_i$ and $p_i$, as a center. We obtained a sequence of segments $s_i \in W(p_i)$ passing through $p_i$ of $d$-length $2\epsilon$ so that the sequence of segments $\text{dev}(\vartheta_i(s_i))$ in $\text{dev}(F_1)$ converges to a nontrivial segment $s$ containing $x'$, and $s'$, satisfying $s \subseteq W_{1,\infty} \subseteq \text{dev}(M_{h,\infty} \cap F_1)$.

Since $s$ is a nontrivial segment, the $d$-length of $h(\vartheta_i)(\text{dev}(s_i))$ is bounded below by a positive constant $\delta$ independent of $i$. Since $h(\vartheta_i)(\text{dev}(s_i))$ is a subset of the
(n - 1)-simplex $\text{dev}(F_1)$, which is a simply convex compact set, the $d$-length of $h(\vartheta_i)(\text{dev}(s_i))$ is bounded above by $\pi - \delta'$ for some small positive constant $\delta'$. Let $s'_i$ be the maximal segment in $W'(p_i)$ including $s_i$. Then the $d$-length of $h(\vartheta_i)(\text{dev}(s'_i))$ also belongs to the interval $[\delta, \pi - \delta']$.

Lemma 4.9 — Let $S^1$ be a great circle and $o, s, p, q$ distinct points on a segment $I$ in $S^1$ of $d$-length $< \pi$ with endpoints $o, s$ and $p$ between $o$ and $q$. Let $f_i$ be a sequence of projective maps $I \to S^n$ so that $d(f_i(o), f_i(s))$ and $d(f_i(p), f_i(q))$ lie in the interval $[\eta, \pi - \eta]$ for some positive constant $\eta$ independent of $i$. Then all of the $d$-distances between $f_i(o), f_i(s), f_i(p)$, and $f_i(q)$ are bounded below by a positive constant independent of $i$.

Proof. — Recall the well-known formula for cross-ratios (see [7]):

$$[f_i(o), f_i(s); f_i(q), f_i(p)] = \frac{\sin(d(f_i(o), f_i(q))) \sin(d(f_i(s), f_i(p)))}{\sin(d(f_i(s), f_i(q))) \sin(d(f_i(o), f_i(p)))}.$$ 

Suppose that $d(f_i(o), f_i(p)) \to 0$. Then since

$$d(f_i(o), f_i(q)) = d(f_i(o), f_i(p)) + d(f_i(p), f_i(q)) \geq \eta,$$

$$d(f_i(o), f_i(s)) \leq d(f_i(o), f_i(s)) \leq \pi - \eta,$$

it follows that $\sin(d(f_i(o), f_i(q)))$ is bounded below and above by $\sin(\eta)$ and 1 respectively. Similarly, so is $\sin(d(f_i(s), f_i(p)))$. Therefore, the right side of the equation goes to $+\infty$, while the left side remains constant since $f_i$ is projective. This is a contradiction, and $d(f_i(o), f_i(p))$ is bounded below by a positive constant.
Similarly, we can show that \( \mathbf{d}(f_1(s), f_1(q)) \) is bounded below by a positive constant. The conclusion follows from these two statements. \( \square \)

Let \( S^1 \) be the unit circle in the plane \( \mathbb{R}^2 \). Let \( \theta, -\pi/2 < \theta < \pi/2 \), denote the point of \( S^1 \) corresponding to the unit vector having an oriented angle of \( \theta \) with \((1,0)\) in \( \mathbb{R}^2 \). Since \( s_i \) and \( s'_i \) are the diameters of balls of \( \mathbf{d} \)-radius \( \epsilon \) and \( 2\epsilon \) with center \( p_i \) respectively, for the segment \([-2\epsilon, 2\epsilon]\) consisting of points \( \theta \) satisfying \(-2\epsilon \leq \theta \leq 2\epsilon \) in \( S^1 \), we parameterize \( s'_i \) by a projective map \( f_i : [-2\epsilon, 2\epsilon] \to s'_i \), isometric with respect to \( \mathbf{d} \), so that the endpoints of \( s'_i \) correspond to \(-2\epsilon \) and \( 2\epsilon \), the endpoints of \( s_i \) to \(-\epsilon \) and \( \epsilon \), and \( p_i \) to 0.

Lemma 4.9 applied to \( k_i = h(\vartheta_i) \circ \mathbf{dev} \circ f_i \) shows that

\[
\mathbf{d}(k_i(2\epsilon), k_i(\epsilon)) \quad \text{and} \quad \mathbf{d}(k_i(-2\epsilon), k_i(-\epsilon))
\]

are bounded below by a positive constant since \( \mathbf{d}(k_i(\epsilon), k_i(-\epsilon)) \) and \( \mathbf{d}(k_i(2\epsilon), k_i(-2\epsilon)) \) are bounded below by a positive number \( \delta \) and above by \( \pi - \delta \). Since \( k_i(2\epsilon) \) and \( k_i(-2\epsilon) \) are endpoints of \( h(\vartheta_i)(\mathbf{dev}(s'_i)) \) and \( k_i(\epsilon) \) and \( k_i(-\epsilon) \) those of \( h(\vartheta_i)(\mathbf{dev}(s_i)) \), a subsequence of \( h(\vartheta_i)(\mathbf{dev}(s'_i)) \) converges to a segment \( s' \) in \( \mathbf{dev}(F_1) \) including \( s \) in its interior. Hence, \( s' \) contains \( x' \) in its interior.

Since \( s'_i \) is a subset of \( F_{2\epsilon} \), a compact subset of \( M_h \), it follows that the corresponding subsequence of \( \vartheta_i(s'_i) \) is ideal in \( F_1 \). Hence \( s' \subset \mathbf{dev}(F_1 \cap M_{h,\infty}) \subset K \) by Proposition 3.15. Since \( x' \) is not an endpoint of \( s' \) but an interior point, this contradicts our earlier choice of \( x' \) as an exposed point of \( K \). \( \square \)

Since \( W_{\infty} \) consists of a point, it follows that the sequence of the \( \mathbf{d} \)-diameter of \( h(\vartheta_i)(\mathbf{dev}(W(p_i))) \) converges to zero, and the sequence converges to the singleton \( \{x'\} \).

Let us introduce a \( \mathbf{d} \)-isometry \( g_i \), which is a real projective automorphism of \( S^n \), for each \( i \) so that each \( g_i(\mathbf{dev}(W(p_i))) \) is a subset of the great sphere \( S^{n-1} \) including \( \mathbf{dev}(F_1) \), and hence \( h(\vartheta_i) \circ g_i^{-1} \) acts on \( S^{n-1} \). We may assume without loss of generality that the the sequence of \( \mathbf{d} \)-isometries \( g_i \) converges to an isometry \( g \) of \( S^n \). Thus, \( h(\vartheta_i) \circ g_i^{-1}(g_i(\mathbf{dev}(W(p_i)))) \) converges to \( x' \), and \( g_i \circ h(\vartheta_i)^{-1}(\mathbf{dev}(F_1)) \) converges to \( g(F_{1,\infty}) \) by what we required in the beginning of the pull-back process. By Proposition B.1, we see that \( g(F_{1,\infty}) \) is an \((n-1)\)-hemisphere, and we are done.
CHAPTER 5

THE TRANSVERSAL INTERSECTION OF

\( n \)-CRESCENTS

From now on, we will assume that \( M \) is compact and with totally geodesic or empty boundary. We will discuss about the transversal intersection of \( n \)-crescents, generalizing that of crescents in two-dimensions \([10]\).

First, we will show that if two hemispheric \( n \)-crescents overlap, then they are equal. For transversal intersection of two bihedral \( n \)-crescents, we will follow Section 2.6 of \([10]\).

Our principal assumption is that \( M \) is not projectively diffeomorphic to an open \( n \)-hemisphere or \( n \)-bihedron, which will be sufficient for the results of this section to hold (see Remark 4.7). This is equivalent to requiring that \( \tilde{M} \) is not projectively diffeomorphic to these. This will be our assumption in Chapters 5 to 8. In applying the results of these Chapters in Chapters 9 and 10 we need this assumption also.

For the following theorem, we may even relax this condition even further:

**Theorem 5.1.** — Suppose that \( M_h \) is not projectively diffeomorphic to an open hemisphere. Suppose that \( R_1 \) and \( R_2 \) are two overlapping \( n \)-crescents that are hemispheres. Then \( R_1 = R_2 \), and hence \( \nu_{R_1} = \nu_{R_2} \) and \( \alpha_{R_1} = \alpha_{R_2} \).

**Proof.** — We use Lemma 5.2 as in \([10]\). By Proposition 3.9, \( \text{dev}(R_1) \cup R_2 \) is an imbedding onto the union of two \( n \)-hemispheres \( \text{dev}(R_1) \) and \( \text{dev}(R_2) \) in \( S^n \). If \( R_1 \) is not equal to \( R_2 \), then \( \text{dev}(R_1) \) differs from \( \text{dev}(R_2) \), \( \text{dev}(R_1) \) and \( \text{dev}(R_2) \) meet each other in a convex \( n \)-bihedron, \( \text{dev}(R_1) \cup \text{dev}(R_2) \) is homeomorphic to an \( n \)-ball, and the boundary \( \delta(\text{dev}(R_1) \cup \text{dev}(R_2)) \) is the union of two \((n-1)\)-hemispheres meeting each other in a great \((n-1)\)-sphere \( S^{n-2} \).

Since \( \alpha_{R_1} \) and \( \alpha_{R_2} \) are disjoint from any of \( R_1^* \) and \( R_2^* \) respectively, the images of \( \alpha_{R_1} \) and \( \alpha_{R_2} \) do not intersect any of \( \text{dev}(R_1^*) \) and \( \text{dev}(R_2^*) \) respectively by Proposition 3.9. Therefore, \( \text{dev}(\alpha_{R_1}) \) and \( \text{dev}(\alpha_{R_2}) \) are subsets of \( \delta(\text{dev}(R_1) \cup \text{dev}(R_2)) \). Since they are open \((n-1)\)-hemispheres, the complement of \( \text{dev}(\alpha_{R_1}) \cup \text{dev}(\alpha_{R_2}) \) in \( \delta(\text{dev}(R_1) \cup \text{dev}(R_2)) \) equals \( S^{n-2} \), and \( \text{dev}(\alpha_{R_1}) \cup \text{dev}(\alpha_{R_2}) \) is dense in \( \delta(\text{dev}(R_1) \cup \text{dev}(R_2)) \). Since \( \text{dev}(R_1) \cup R_2 \) is an imbedding, it follows that \( R_1 \cup R_2 \) is an \( n \)-ball, and the closure of \( \alpha_{R_1} \cup \alpha_{R_2} \) equals \( \delta(R_1 \cup R_2) \). Hence, \( \delta(R_1 \cup R_2) \subset M_h, \infty \). By
Lemma 3.17 it follows that $M_h = R_1^\circ \cup R_2^\circ$, and $M_h$ is boundaryless. By Lemma 5.2, this is a contradiction. Hence, $R_1 = R_2$.

Lemma 5.2 — Let $N$ be a closed real projective $n$-manifold. Suppose that $\text{dev} : N_h \to S^n$ is an imbedding onto the union of $n$-hemispheres $H_1$ and $H_2$ meeting each other in an $n$-bihedron or an $n$-hemisphere. Then $H_1 = H_2$, and $N_h$ is projectively diffeomorphic to an open $n$-hemisphere.

Proof. — Let $(\text{dev}, h)$ denote the development pair of $N$, and $\Gamma$ the deck transformation group. As $\text{dev}|N_h$ is a diffeomorphism onto $H_1^\circ \cup H_2^\circ$, a simply connected set, we have $N_h = \tilde{N}$.

Suppose that $H_1 \neq H_2$. Then $H_1 \cup H_2$ is bounded by two $(n-1)$-hemispheres $D_1$ and $D_2$ meeting each other on a great sphere $S^{n-2}$, their common boundary. Since the interior angle of intersection of $D_1$ and $D_2$ is greater than $\pi$, $\delta H_i - D_i$ is an open hemisphere included in $\text{dev}(\tilde{N})$ for $i = 1, 2$. Defining $O_i = \delta H_i - D_i$ for $i = 1, 2$, we see that $O_1 \cup O_2$ is $h(\Gamma)$-invariant since $\delta(H_1 \cup H_2)$ is $h(\Gamma)$-invariant. This means that the inverse image $\text{dev}^{-1}(O_1 \cup O_2)$ is $\Gamma$-invariant.

Let $O'_1 = \text{dev}^{-1}(O_1)$. Then elements of $\Gamma$ either act on each of $O'_1$ and $O'_2$ or interchange them. Thus, $\Gamma$ includes a subgroup $\Gamma'$ of index one or two acting on each of $O'_1$ and $O'_2$. Since $N_h$ is a simply connected open ball, and so is $O'_1$, it follows that the $n$-manifold $\tilde{N}/\Gamma'$ and an $(n-1)$-manifold $O'_1/\Gamma'$ are homotopy equivalent. Since $\tilde{N}/\Gamma'$ is a finite cover of a closed manifold $N$, $\tilde{N}/\Gamma'$ is a closed manifold. Since the dimensions of $\tilde{N}/\Gamma'$ and $O'_1/\Gamma'$ are not the same, this is shown to be absurd by computing $\mathbb{Z}_2$-homologies. Hence we obtain that $H_1 = H_2$, and since $\text{dev}(\tilde{N})$ equals the interior of $H_1$, $\tilde{N}$ is diffeomorphic to an open $n$-hemisphere.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure5.1.png}
\caption{Transversal intersections in dimension two.}
\end{figure}
Suppose that $R_1$ is an $n$-crescent that is an $n$-bihedron. Let $R_2$ be another bihedral $n$-crescents with sets $\alpha_{R_2}$ and $\nu_{R_2}$. We say that $R_1$ and $R_2$ intersect **transversally** if $R_1$ and $R_2$ overlap and the following conditions hold ($i = 1$, $j = 2$; or $i = 2$, $j = 1$):

1. $\nu_{R_i} \cap \nu_{R_j}$ is an $(n-2)$-dimensional hemisphere.
2. For the intersection $\nu_{R_i} \cap \nu_{R_j}$ denoted by $H$, $H$ is an $(n-2)$-hemisphere, $H^c$ is a subset of the interior $\nu_{R_i}^c$, and $\text{dev}(\nu_{R_i})$ and $\text{dev}(\nu_{R_j})$ intersect transversally at $\text{dev}(H)$.
3. $\nu_{R_i} \cap R_j$ is a tame $(n-1)$-bihedron with boundary the union of $H$ and an $(n-2)$-hemisphere $H'$ in the closure of $\alpha_{R_j}$ with its interior $H'^c$ in $\alpha_{R_j}$.
4. $\nu_{R_i} \cap R_j$ is the closure of a component of $\nu_{R_i} - H$ in $M_h$.
5. $R_i \cap R_j$ is the closure of a component of $R_j - \nu_{R_i}$.
6. Both $\alpha_{R_i} \cap \alpha_{R_j}$ and $\alpha_{R_i} \cup \alpha_{R_j}$ are homeomorphic to open $(n-1)$-dimensional balls, which are locally totally geodesic under $\text{dev}$.

Note that since $\alpha_{R_i}$ is tame, $\alpha_{R_i} \cap \alpha_{R_j}$ is tame. (See Figures 5.1 and 5.2.)

By Corollary 5.8, the above condition mirrors the property of intersection of $\text{dev}(R_1)$ and $\text{dev}(R_2)$ where $\text{dev}(\alpha_{R_1})$ and $\text{dev}(\alpha_{R_2})$ are included in a common great sphere $S^{n-1}$ of dimension $(n-1)$, $\text{dev}(R_1)$ and $\text{dev}(R_2)$ included in a common $n$-hemisphere bounded by $S^{n-1}$ and $\text{dev}(\nu_{R_1})^c$ and $\text{dev}(\nu_{R_2})^c$ meet transversally (see Proposition 3.9). Conversely, if the images of $R_1$ and $R_2$ satisfy these conditions, and $R_1$ and $R_2$ overlap, then $R_1$ and $R_2$ intersect transversally.

**Example 5.3.** — In the example 3.12, $R$ is an $n$-crescent with the closure of the plane $P$ given by the equation $x_1 + \cdots + x_n = 0$ equal to $\nu_R$. $\alpha_R$ equals the interior of the intersection of $R$ with $\delta H$. $\nu_S$ is the closure of the plane given by $x_1 = 0$ and $\alpha_S$ the interior of the intersection of $S$ with $\delta H$. Clearly, $R$ and $S$ intersect transversally.

Using the reasoning similar to Section 2.6. of [10], we obtain:

**Theorem 5.4.** — Suppose that $R_1$ and $R_2$ are overlapping. Then either $R_1$ and $R_2$ intersect transversally or $R_1 \subset R_2$ or $R_2 \subset R_1$.

**Remark 5.5.** — In case $R_1$ is a proper subset of $R_2$, we see easily that $\alpha_{R_1} = \alpha_{R_2}$ since the sides of $R_1$ in $M_{h,\infty}$ must be in one of $R_2$. Hence, we also see that $\nu_{R_1} \subset R_2$ as the topological boundary of $R_1$ in $R_2$ must lie in $\nu_{R_1}$.

The proof is entirely similar to that in [10]. A heuristic reason that the theorem holds is as follows (due to the referee): We show that $\text{dev}(R_1 \cup R_2)$ is an imbedding onto $\text{dev}(R_1) \cup \text{dev}(R_2)$ as $R_1$ and $R_2$ overlap. As $\alpha_{R_1}$ and $\alpha_{R_2}$ are subsets of $M_{h,\infty}$, their images $\text{dev}(\alpha_{R_1})$ and $\text{dev}(\alpha_{R_2})$ are disjoint from $\text{dev}(R_1)^c$ and $\text{dev}(R_2)^c$. Among all combinatorial types of configurations of bihedrons $\text{dev}(R_1)$ and $\text{dev}(R_2)$ in $S^n$, the configuration satisfying this condition should be the one described above. For reasons of rigor, we present the following somewhat nonintuitive arguments; however, a parallel argument purely based on the images of $R_1$ and $R_2$ in $S^n$ is also possible.

Assume that we have $i = 1$ and $j = 2$ or have $i = 2$ and $j = 1$, and $R_1 \not\subset R_2$ and $R_2 \not\subset R_1$. Since $\text{Cl}(\alpha_{R_i}) \subset M_{h,\infty}$, Corollary 3.11 and Proposition 3.9 imply that $R_j$...
dips into \((R_i, \nu_{R_i})\), a point of view we shall hold for a while. Hence, the following statements hold:

- \(\nu_{R_i} \cap R_j\) is a convex \((n - 1)\)-ball \(\alpha_i\) such that

\[
\delta \alpha_i \subset \delta R_j, \alpha_i^o \subset R_j^o.
\]  

- \(R_i \cap R_j\) is the convex \(n\)-ball that is the closure of a component of \(R_j - \alpha_i\).

Since \(\alpha_i^o\) is disjoint from \(\nu_{R_i}\), \(\alpha_i^o\) is a subset of a component \(C\) of \(\nu_{R_i} - \nu_{R_j}\).

**Lemma 5.6** — If \(\nu_{R_i}\) and \(\nu_{R_j}\) meet, then they do so transversally, i.e., their images under \(\text{dev}\) meet transversally. If \(\nu_{R_i}\) and \(\alpha_{R_j}\) meet, then they do so transversally.

**Proof.** — Suppose that \(\nu_{R_i}\) and \(\nu_{R_j}\) meet and they are tangential. Then \(\text{dev}(\nu_{R_i})\) and \(\text{dev}(\nu_{R_j})\) both lie on a common great \((n - 1)\)-sphere in \(S^n\). Since \(\text{dev}(R_j)\) lies in an \(n\)-hemisphere bounded by this sphere, \(\nu_{R_i} \cap \nu_{R_j} = \nu_{R_i} \cap R_j\) by Proposition 3.9. Since \(\nu_{R_i} \cap R_j\) includes an open \((n - 1)\)-ball \(\alpha_i^o\), this contradicts \(\alpha_i^o \subset R_j^o\).

Suppose that \(\nu_{R_i}\) and \(\alpha_{R_j}\) meet and they are tangential. Then \(\nu_{R_i} \cap \text{Cl}(\alpha_{R_j}) = \nu_{R_i} \cap R_j\) as before, which leads to contradiction similarly.

We now determine a preliminary property of \(\alpha_i\). Since \(\alpha_i\) is a convex \((n - 1)\)-ball in \(\nu_{R_i}\) with topological boundary in \(\delta R_i \cup \delta R_j\), we obtain

\[
\delta \alpha_i \subset \delta \nu_{R_i} \cup (\delta R_j \cap \nu_{R_i}^o) \\
\subset \delta \nu_{R_i} \cup (\nu_{R_j} \cap \nu_{R_i}^o) \cup (\alpha_{R_j} \cap \nu_{R_i}^o).
\]
Hence, we have
\[ \delta \alpha_i = (\delta \alpha_i \cap \delta v_{R_i}) \cup (\delta \alpha_i \cap v_{R_j} \cap v_{R_i}^c) \cup (\delta \alpha_j \cap \alpha_{R_j} \cap v_{R_i}^c). \]

If \( \alpha_{R_j} \) meets \( v_{R_i}^c \), then since \( \alpha_{R_j} \) is transversal to \( v_{R_i}^c \) by Lemma 5.6, \( \alpha_{R_j} \) must intersect \( R_i^o \) by Proposition 3.9. Since \( \alpha_{R_j} \subset M_{h,\infty} \), this is a contradiction. Thus, 
\[ \alpha_{R_j} \cap v_{R_i}^c = \emptyset. \]
We conclude
\[ (5.2) \quad \delta \alpha_i = (\delta \alpha_i \cap \delta v_{R_i}) \cup (\delta \alpha_i \cap v_{R_j} \cap v_{R_i}^c). \]

Before continuing the proof, let us state a few easy spherical geometry facts: Given an \( i \)-hemisphere \( J \) in \( S^n \), if \( K \) is a great sphere in \( J \), then \( K \) is included in \( \delta J \). Thus if \( K \) is a compact convex set containing a point of \( J^o \), then \( K \) must be an \( j \)-ball for some \( j \), \( 0 \leq j \leq i \), by Proposition 2.6.

An \((i-1)\)-hemisphere \( K, i \geq 1 \), in \( J \) has its boundary in \( \delta J \). If \( K \) contains a point of \( J^o \), then \( K \) equals \( J \cap L \) for a great \((i-1)\)-sphere \( L \), and \( J^o - K \) has exactly two components which are convex. Since the closures of the components includes \( K \), Lemma 2.5 shows that the closures of two components are \( i \)-bihedrons.

Suppose that \( K \) is a convex \((i-1)\)-ball in \( J \) meeting \( J^o \). Then \( K \) must be a convex subset of \( J \cap L \) for a great \((i-1)\)-sphere \( L \). If \( \delta K \) meets \( J^o \), then \( J \cap L \) is a \((i-1)\)-hemisphere which includes \( K \) as a proper convex subset. Thus \( J^o - K \) can have only one component. Hence, if \( K \) meets \( J^o \), and \( J^o - K \) has at least two components, then \( K \) must be an \((i-1)\)-hemisphere. In this case, it is obvious that \( K^o \subset J^o \).

Let us denote by \( H \) the set \( v_{R_i} \cap v_{R_j} \). Consider for the moment the case where \( v_{R_i} \cap v_{R_j} \neq \emptyset \). Since \( \text{dev}(H) \) is a compact convex set and is included in an \((n-1)\)-hemisphere \( \text{dev}(v_{R_i}) \), Lemma 5.6 and above paragraphs show that \( \text{dev}(H) \) is a compact convex \((n-2)\)-ball. Thus, \( H \) is a tame topological \((n-2)\)-ball by Proposition 3.9.

If \( H \) has boundary points, i.e., points of \( \delta H \), in \( v_{R_i}^c \), then \( v_{R_i}^c - H \) would have only one component. Since the boundary of \( \alpha_i \) in \( v_{R_i}^c \) is included in \( H \) by equation 5.2, \( \alpha_i^c \) is dense in \( v_{R_i}^c \), implying \( \alpha_i = v_{R_i}^c \). Since \( \alpha_i^c \) is a subset of \( R_i^o \) by equation 5.1, \( v_{R_i}^c \) is a subset of \( R_i^o \), which contradicts our momentary assumption. It follows that \( H \) is an \((n-2)\)-hemisphere with boundary in \( \delta v_{R_i} \) and the interior \( H^o \) in \( v_{R_i}^c \), and \( H \) separates \( v_{R_i} \) into two convex components, and the closures of each of them are \((n-1)\)-bihedrons. Obviously, \( \alpha_i^c \) is the closure of one of the components.

We need to consider only the following two cases by interchanging \( i \) and \( j \) if necessary:
(i) \( v_{R_j}^c \cap v_{R_i}^c \neq \emptyset \).
(ii) \( v_{R_j} \cap v_{R_i}^c = \emptyset \) or \( v_{R_i} \cap v_{R_j}^c = \emptyset \).

(i) Since \( \alpha_i \) is the closure of a component of \( v_{R_i} - H \), \( \alpha_i \) is an \((n-1)\)-bihedron bounded by an \((n-2)\)-hemisphere \( H \) and another \((n-2)\)-hemisphere \( H' \) in \( \delta v_{R_i} \). Since \( H' \) is a subset of the closure of \( \alpha_{R_j} \), \( H' \) is a subset of \( M_{h,\infty} \) and hence disjoint from \( R_j \) while \( R_j \subset M_h \).

Since \( H' \) is a subset of \( R_j \), we have \( H' \subset \delta R_j \). Since \( \nu_{R_i} \) is transversal to \( \nu_{R_j} \), \( H' \) is not a subset of \( v_{R_j} \); thus, \( H'^o \) is a subset of \( \alpha_{R_j} \), and \( H' \neq \text{Cl}(\alpha_{R_j}) \) by Proposition 3.9. This completes the proof of the transversality properties (1)-(4) in case (i).
(5) By dipping intersection properties, $R_i \cap R_j$ is the closure of a component of $R_j - \alpha_i$ and hence that of $R_j - \nu_{R_j}$.

(6) Since $H'^o$ is a subset of $\alpha_{R_j}$, $\alpha_{R_j} - H'$ has two components $\beta_1$ and $\beta_2$, homeomorphic to open $(n - 1)$-balls. By (5), we may assume without loss of generality that $\beta_1$ is a subset of $R_i$, and $\beta_2$ is disjoint from $R_i$. Since $\beta_1 \subset M_{\nu, \infty}$, we have $\beta_1 \subset \delta R_i$. As $\beta_1$ is a component of $\alpha_{R_j}$ removed with $H'$, we see that $\beta_1$ is an open $(n - 1)$-bihedron bounded by $H'$ in $\delta \nu_{R_i}$ and an $(n - 2)$-hemisphere $H''$ in $\delta \nu_{R_j}$ (see Figure 5.3).

Since (i) holds for $i$ and $j$ exchanged, we obtain, by a paragraph above the condition (i), $H''$ belongs to $\nu_{R_i}^o \cap \nu_{R_j}^o$.

Since the closure of $\beta_1$ belongs to $R_i$, we obtain that $H'' \subset R_i$ and $H''$ is a subset of $\alpha_j$, where $\alpha_j = \nu_{R_j} \cap R_i$. As $H''$ is a subset of $\delta \nu_{R_i}$, and $\alpha_j$ is the closure of a component of $\nu_{R_i}$ removed with $H$, we obtain $H'' \subset \delta \alpha_j$.

By (1)-(4) with values of $i$ and $j$ exchanged, $\alpha_j$ is an $(n - 1)$-bihedron bounded by $H$ and an $(n - 2)$-hemisphere $H''$ with interior in $\alpha_{R_i}$, and is the closure of a component of $\nu_{R_j} \cap H$. Since $H''$ is an $(n - 2)$-hemisphere in $\delta \alpha_j$, and so is $H''$, it follows that $H'' = H''$.

Since $\beta_1$ has the boundary the union of $H'$ in $\delta \nu_{R_i}$ and $H''$, $H'' = H''$, with interior in $\alpha_{R_i}$, and $\beta_1$ is a convex subset of $R_i$, looking at the bihedron $\text{dev}(\alpha_{R_i})$ and the geometry of $S^n$ show that $\beta_1 \subset \alpha_{R_i}$. Thus, we obtain $\beta_1 \subset \alpha_{R_i} \cap \alpha_{R_j}$. We see that $\text{dev}(\alpha_{R_i})$ and $\text{dev}(\alpha_{R_j})$ are subsets of a common great $(n - 1)$-sphere; it follows easily by Proposition 3.9 that $\beta_1 = \alpha_{R_i} \cap \alpha_{R_j}$. Hence, $\alpha_{R_i} \cap \alpha_{R_j}$ and $\alpha_{R_i} \cup \alpha_{R_j}$ are homeomorphic to open $(n - 1)$-balls, and under $\text{dev}$ they map to totally geodesic $(n - 1)$-balls in $S^n$.

(ii) Assume $\nu_{R_i}^o \cap \nu_{R_j} = \emptyset$ without loss of generality. Then $H$ is a subset of $\delta \nu_{R_j}$. Since $R_i$ dips into $(R_j, \nu_{R_j})$, we have that $\alpha_j \neq \emptyset$. Since the boundary of $\alpha_j$ in $\nu_{R_j}^o$, ...
is included in $H$ (see equation 5.2), we have $\alpha_j = \nu_{R_j}$ and $\nu_{R_j} \subset R_i$. Since $\nu_{R_j}$ is an $(n-1)$-hemisphere, and $R_i$ is an $n$-bihedron, the uniqueness of $(n-2)$-spheres in an $n$-bihedron (Proposition 2.4) shows that $\delta \nu_{R_j} = \delta \nu_{R_j}$. Thus, the closures of components of $R_i - \nu_{R_j}$ are $n$-bihedrons with respective boundaries $\alpha_{R_i} \cup \nu_{R_j}$ and $\nu_{R_i} \cup \nu_{R_j}$. By Corollary 3.11, $R_i \cap R_j$ is the closure of either the first component or the second one.

In the first case, $R_i \cap R_j$ is an open subset of $R_i$. Since $R_i$ is open in $M_i$, the closure of $R_i$ in $M_i$ equals $R_i \cup (\nu_{R_i} \cap M_i) = R_i \cap M_i$. Since $\nu_{R_i}$, which includes $\nu_{R_i} \cap M_i$, does not meet $R_j$ in the first case being in the other component of $R_i - \nu_{R_i}$, we see that the intersection of the closure of $R_i$ in $M_i$ with $R_j$ is as same as $R_i \cap R_j$. Thus, $R_i \cap R_j$ is open and closed subset of $R_i$. Hence $R_i \subset R_i$ and $R_i \subset R_j$. This contradicts our hypothesis.

In the second case, $\text{dev}(R_i) \cup R_j$ is a homeomorphism to $\text{dev}(R_i) \cup \text{dev}(R_j)$. As $\alpha_{R_i}$ and $\alpha_{R_j}$ are subsets of $M_{i, \infty}$, their images under $\text{dev}$ may not meet that of $\text{dev}(R_i) \cup \text{dev}(R_j)$. Hence, $\text{dev}(R_i) \cup \text{dev}(R_j)$ is an $n$-ball bounded by two $(n-1)$-hemispheres $\text{dev}(\text{Cl}(\alpha_{R_i}))$ and $\text{dev}(\text{Cl}(\alpha_{R_j}))$. We obtain that $R_i \cup R_j$ is the $n$-ball bounded by two $(n-1)$-dimensional hemispheres $\text{Cl}(\alpha_{R_i})$ and $\text{Cl}(\alpha_{R_j})$.

Since $\text{Cl}(\alpha_{R_i})$ and $\text{Cl}(\alpha_{R_j})$ are subsets of $M_{i, \infty}$, Lemma 3.17 shows that $M_{i, \infty} = R_i \cup R_j$ and $M_{i, \infty} = R_i \cup R_j$; thus, $M_{i, \infty} = M$ and $M$ is a closed manifold. The image $\text{dev}(R_i) \cup \text{dev}(R_j)$ is bounded by two $(n-1)$-hemispheres meeting each other on a great sphere $S^{n-2}$, their common boundary. Since $M_{i, \infty}$ is not projectively diffeomorphic to an open $n$-hemisphere or an open $n$-bihedron, the interior angle of intersection of the two boundary $(n-1)$-hemispheres should be greater than $\pi$. However, Lemma 5.2 contradicts this.

**Remark 5.7.** — Using the same proof as above, we may drop the condition on the Euler characteristic from Theorem 2.6 of [10] if we assume that $\hat{M}$ is not projectively diffeomorphic to an open 2-hemisphere or an open lune. This is weaker than requiring that the Euler characteristic of $M$ is less than zero. So, our theorem is an improved version of Theorem 2.6 of [10].

**Corollary 5.8.** — Let $R_1$ and $R_2$ be bihedral $n$-crecents and they overlap. Then the following statements hold:

- $\text{dev}(\alpha_{R_1})$ and $\text{dev}(\alpha_{R_2})$ are included in a common great $(n-1)$-sphere $S^{n-1}$.
- $\text{dev}(\nu_{R_1})$ and $\text{dev}(\nu_{R_2})$ meet in an $(n-2)$-hemisphere transversally.
- $\text{dev}(R_1)$ and $\text{dev}(R_2)$ are subsets of a common great $n$-hemisphere bounded by $S^{n-1}$.
- $\text{dev}(R_i - \text{Cl}(\alpha_{R_i}))$ is a subset of the interior of this $n$-hemisphere for $i = 1, 2$. 

\[\square\]
CHAPTER 6

HEMISPHERIC $n$-CRESCENTS AND TWO-FACED SUBMANIFOLDS

In this chapter, we introduce the two-faced submanifolds arising from hemispheric $n$-crescents. We showed above that if two hemispheric $n$-crescents overlap, then they are equal. We show that if two hemispheric $n$-crescents meet but do not overlap, then they meet at the union of common components of their $n$-boundaries, which we call copied components. The union of all copied components becomes a properly imbedded submanifold in $M$, and covers a closed submanifold in $M$, which is said to be the two-faced submanifold.

**Lemma 6.1** — Let $R$ be an $n$-crescent. A component of $\delta M_h$ is either disjoint from $R$ or is a component of $\nu_R \cap M_h$. Moreover, a tiny ball $B(x)$ of a point $x$ of $\delta M_h$ is a subset of $R$ if $x$ belongs to $\nu_R \cap M_h$, and, consequently, $x$ belongs to the topological interior $\text{int} R$.

**Proof.** — If $x \in \delta M_h$, then a component $F$ of the open $(n-1)$-manifold $\nu_R \cap M_h$ intersects $\delta M_h$ tangentially, and by Lemma 3.1, it follows that $F$ is a subset of $\delta M_h$. Since $F$ is a closed subset of $\nu_R \cap M_h$, $F$ is a closed subset of $\delta M_h$. Since $F$ is an open manifold, $F$ is open in $\delta M_h$. Thus, $F$ is a component of $\delta M_h$.

Since $x \in \text{int} B(x)$, $B(x)$ and $R$ overlap. As $\text{Cl}(\alpha_R)$ is a subset of $M_h$, we have $\text{bd} \alpha_R \cap B(x) \subseteq \nu_R$ and $\nu_R \cap B(x) = F \cap B(x)$ for a component $F$ of $\nu_R \cap M_h$ containing $x$. Since $F$ is a component of $\delta M_h$, we obtain $F \cap B(x) \subset \delta B(x)$; since we have $\text{bd} F \cap B(x) \subset \delta B(x)$, it follows that $B(x)$ is a subset of $R$.

Suppose that $M_h$ includes an $n$-crescent $R$ that is an $n$-hemisphere. Then $M_h \cap R$ is a submanifold of $M_h$ with boundary $\delta R \cap M_h$. Since $R$ is an $n$-crescent, $\delta R \cap M_h$ equals $\nu_R \cap M_h$. Let $B_R$ denote $\nu_R \cap M_h$.

Let $S$ be another hemispheric $n$-crescent, and $B_S$ the set $\nu_S \cap M_h$. By Theorem 5.1, we see that either $S \cap R^c = \emptyset$ or $S = R$. Suppose that $S \cap R \neq \emptyset$ and $S$ does not equal $R$. Then $B_S \cap B_R \neq \emptyset$. Let $x$ be a point of $B_S \cap B_R$ and $B(x)$ the tiny ball of $x$. Since $\text{int} B(x) \cap R \neq \emptyset$, it follows that $B(x)$ dips into $(R, \nu_R)$ or $B(x)$ is a subset of $R$ by Lemma 3.13. Similarly, $B(x)$ dips into $(S, \nu_S)$ or $B(x)$ is a subset of $S$. If $B(x)$ is a subset of $R$, then $S$ intersects the interior of $R$. Theorem 5.1 shows $S = R$, a contradiction. Therefore, $B(x)$ dips into $(R, \nu_R)$ and similarly into $(S, \nu_S)$. If $\nu_R
and $\nu_s$ intersect transversally, then $R$ and $S$ overlap, implying a contradiction $S = R$. Therefore, $B_S$ and $B_R$ intersect tangentially at $x$.

If $x \in \delta M_h$, Lemma 6.1 shows that $B(x)$ is a subset of $R$. This contradicts a result of the above paragraph. Thus, $x \not\in M_h^o$. Hence, we conclude that $B_R \cap B_S \subset M_h^o$.

Since $B_R$ and $B_S$ are closed subsets of $M_h$, and $B_R$ and $B_S$ are totally geodesic and intersect tangentially at $x$, it follows that $B_R \cap B_S$ is an open and closed subset of $B_R$ and $B_S$ respectively. Thus, for components $A$ of $B_R$ and $B$ of $B_S$, either we have $A = B$ or $A$ and $B$ are disjoint. Therefore, we have proved:

**Proposition 6.2.** — Given two hemispheric $n$-crescents $R$ and $S$, we have either $R$ and $S$ disjoint, or $R$ equals $S$, or $R \cap S$ equals the union of common components of $\nu_R \cap M_h$ and $\nu_s \cap M_h$ in $M_h^o$.

Readers may easily find examples where $\nu_R \cap M_h$ and $\nu_s \cap M_h$ are not equal in the above situations.

**Definition 6.3.** — Given a hemispheric $n$-crescent $T$, we say that a component of $\nu_T \cap M_h$ is copied if it equals a component of $\nu_U \cap M_h$ for some hemispheric $n$-crescent $U$ not equal to $T$.

Let $c_R$ be the union of all copied components of $\nu_R \cap M_h$ for a hemispheric $n$-crescent $R$. Let $A$ denote $\bigcup_{R \in H} c_R$ where $H$ is the set of all hemispheric $n$-crescents in $M_h$. $A$ is said to be the pre-two-faced submanifold arising from hemispheric $n$-crescents.

**Proposition 6.4.** — Suppose that $A$ is not empty. Then $A$ is a properly imbedded totally geodesic $(n-1)$-submanifold of $M_h^o$ and $p|A$ is a covering map onto a closed totally geodesic imbedded $(n-1)$-manifold in $M^o$.

First, given two $n$-crescents $R$ and $S$, $c_R$ and $c_S$ meet either in the union of common components or in an empty set: Let $a$ and $b$ be respective components of $c_R$ and $c_S$ meeting each other. Then $a$ is a component of $\nu R \cap M_h$ and $b$ that of $\nu s \cap M_h$. Since $R \cap S \neq \emptyset$, either $R$ and $S$ overlap or $a = b$ by the above argument. If $R$ and $S$ overlap, $R = S$ and hence $a$ and $b$ must be the identical component of $\nu R \cap M_h$ and hence $a = b$. Therefore, $A$ is a union of mutually disjoint closed path-components that are components of $c_R$ for some $n$-crescent $R$.

Second, given a tiny ball $B(x)$ of a point $x$ of $M_h$, we claim that no more than one path-component of $A$ may intersect int$B(x)$: Let $a$ be a component of $c_R$ intersecting int$B(x)$. Since copied components are subsets of $M_h^o$, $a$ intersects $B(x)^o$ and hence $B(x)$ is not a subset of $R$. By Lemma 3.13, $\nu R \cap B(x)$ is a compact convex $(n-1)$-ball with boundary in bd$B(x)$. Since it is connected, $a \cap B(x) = \nu R \cap B(x)$, and $B(x) \cap R$ is the closure of a component $C_1$ of $B(x) - (a \cap B(x))$ by Corollary 3.11. Since $a$ is copied, it is a component of $\nu S \cap M_h$ for an $n$-crescent $S$ not equal to $R$, and $B(x) \cap S$ is the closure of a component $C_2$ of $B(x) - (a \cap B(x))$. Since $R$ and $S$ do not overlap, it follows that $C_1$ and $C_2$ are the two disjoint components of $B(x) - (a \cap B(x))$.

Suppose that $b$ is a component of $c_T$ for an $n$-crescent $T$ and $b$ intersects int$B(x)$ also. If the $(n-1)$-ball $b \cap B(x)$ intersects $C_1$ or $C_2$, then $T$ overlaps $R$ or $S$ respectively and hence $T = R$ or $T = S$ respectively by Theorem 5.1; therefore, we have $a = b$. This is absurd. Hence $b \cap B(x) \subset a \cap B(x)$ and $T$ overlaps with either $R$ or $S$.  

Since these are hemispheric crescents, we have either $T = R$ or $T = S$ respectively; therefore, $a = b$. We conclude that if $\text{int} B(x) \cap A$ is not empty, then $B(x) \cap A$ equals a compact $(n - 1)$-ball with boundary in $\partial B(x)$.

Since each path-component of $A$ is an open subset of $A$, the above shows that $A$ is a totally geodesic $(n - 1)$-submanifold of $M^n_b$, closed and properly imbedded in $M^n_b$.

Let $p : M_b \to M$ be the covering map. Since $A$ is the deck transformation group invariant, we have $A = p^{-1}(p(A))$ and $pA$ covers $p(A)$. The above results show that $p(A)$ is a closed totally geodesic manifold in $M^o$.

**Definition 6.5.** — The image $p(A)$ for the union $A$ of all copied components of hemispheric $n$-crescents in $M_b$ is said to be the **two-faced** $(n - 1)$-manifold of $M$ arising from hemispheric $n$-crescents (or **type I**).

Each component of $p(A)$ is covered by a component of $A$, i.e., a copied component of $\nu_R \cap M_b$ for some crescent $R$. Since $\alpha_R$ is the union of the open $(n - 1)$-hemispheres in $\delta R$, $\nu_R \cap M_b$ lies in an open $(n - 1)$-hemisphere, i.e., an affine patch in the great $(n - 1)$-sphere $\delta R$. Hence, each component of $p(A)$ is covered by an open domain in $\mathbb{R}^n$, as we mentioned in the introduction.

We end with the following observation:

**Proposition 6.6.** — Suppose that $A = \bigcup_{R \in \mathcal{R}} c_R$. Then $A$ is disjoint from $S^o$ for each hemispheric $n$-crescent $S$ in $M_b$.

**Proof.** — If not, then a point $x$ of $c_R$ meets $S^o$ for some hemispheric $n$-crescent $S$. But if so, then $R$ and $S$ overlap, and $R = S$, a contradiction. $\square$
In this chapter, we will define an equivariant set $\Lambda(R)$ for a bihedral $n$-crescent $R$, which will play the role of hemispheric $n$-crescents in the previous chapter. We discuss its properties which are exactly same as those of its two-dimensional version in [10]. Then we discuss the two-faced submanifold that arises from $\Lambda(R)$'s: We show that $\Lambda(R)$ and $\Lambda(S)$ for two $n$-crescents are either equal or disjoint or meet at their common boundary components in $M_h$. The union of all such boundary components for $\Lambda(R)$ for every bihedral $n$-crescent $R$ is shown to be a totally geodesic properly imbedded submanifold in $M_h$ and cover a closed totally geodesic submanifold of $M$.

We will suppose in this chapter that $M_h$ includes no hemispheric crescent $R$; i.e., we assume that all $n$-crescents in $M_h$ are bihedrons. Two bihedral $n$-crescents in $M_h$ are equivalent if they overlap. This generates an equivalence relation on the collection of all bihedral $n$-crescents in $M_h$; that is, $R \sim S$ if and only if there exists a sequence of bihedral $n$-crescents $R_i$, $i = 1, \ldots, n$, such that $R_1 = R, R_n = S$ and $R_{i-1} \cap R_i \neq \emptyset$ for $i = 2, \ldots, n$.

We define

$$\Lambda(R) := \bigcup_{s \sim R} S, \quad \delta_s \Lambda(R) := \bigcup_{s \sim R} \alpha_s, \quad \Lambda_1(R) := \bigcup_{s \sim R} (S - v_R).$$

**Example 7.1.** — Consider the universal cover $L$ of $H^o - \{O\}$ where $H$ is a 2-hemisphere in $S^2$. Then it has an induced real projective structure with developing map equal to the covering map $c$. There is a nice parameterization $(r, \theta)$ of $L$ where $r$ denotes the $d$-distance of $c(x)$ from $O$ and $\theta(x)$ the oriented total angle from the lift of the positive $x$-axis for $x \in L$, i.e., one obtained by integrating the 1-form lifted from the standard angular form $d\theta$ on the affine space $H^o$. Here $r$ belongs to $(0, \pi/2)$ and $\theta$ to $(-\infty, \infty)$. $L$ is hence a holonomy cover of itself as it is simply connected. $\bar{L}$ may be identified with the universal cover of $H - \{O\}$ with a point $O'$ added to make it a complete space where $O'$ maps to $O$ under the extended developing map $c$. (We use the universal covering space since the holonomy cover gives us uninteresting examples.)
\textbf{CHAPTER 7. BIHEDRAL $n$-CRESCENTS}

We can determine that $\hat{L}_\infty$ equals the union of $\{O^i\}$ and a $d$-infinite geodesic given by equation $d(O^i, x) = \pi/2$, i.e., the inverse image of $\partial H$. A crescent in $L$ is the closure of a lift of an affine half space in $H^\circ - \{O\}$. A special type of a crescent is the closure of the set given by $\theta_0 \leq \theta \leq \theta_0 + \pi$. Given a crescent $R$ in $L$, we see that $\Lambda(R)$ equals $L$.

We may also define another real projective manifold $N$ by an equation $f(\theta) < r < \pi/2$ for a function $f$ with values in $(0, \pi/2)$. Then $N$ equals the closure of $N$ in $L$. Given a crescent $R$ in $N$, we see that $\Lambda(R)$ may not equal to $N$ especially in case $f$ is not a convex function (as seen in polar coordinates). (See Figure 7.1.)

For a higher-dimensional example, let $H$ be a 3-hemisphere in $\mathbb{S}^3$, and $l$ a segment of $d$-length $\pi$ passing through the origin. Let $L$ be the universal cover of $H^\circ - l$. Then $L$ becomes a real projective manifold with developing map the covering map $c : L \to H^\circ - l$. The holonomy cover of $L$ is $L$ itself. The completion $\hat{L}$ of $L$ equals the completion of the universal cover of $H - l$ with $l$ attached to make it a complete space. A 3-crescent is the closure of a lift of an open half space in $H - l$. Given a 3-crescent $R$, $\Lambda(R)$ equals $L$.

We introduce coordinates on $H^\circ$ so that $l^\circ$ is now the $z$-axis. Note that $L$ is parameterized by $(r, \theta, \phi)$ where $r(x)$ equals the $d$-distance from $O$ to $c(x)$, $\phi$ the angle that $Oc(x)$ makes with the positive $z$-axis, and $\theta(x)$ again the integral of the obvious 1-form lifted from the standard angular form $d\theta$ in $\mathbb{R}^3$. We may also define other real projective manifolds by equation $f(\theta, \phi) < r < \pi/2$ for $f : \mathbb{R} \times (0, \pi) \to (0, \pi/2)$. The readers may work out how the completions might look and what $\Lambda(R)$ be when $R$ is a 3-crescent. We remark that for certain $f$ which converges to $\pi/2$ as $\phi \to 0$ or $\pi$, we may have no 3-crescents in the completion of the real projective manifold given by $f$.

Even higher-dimensional examples are given in a similar spirit by removing sets from such covers. After reading this section, the reader can easily see that these are really typical examples of $\Lambda(R)$.

Let us state the properties that hold for these sets: The proofs are straightforward and exactly as in [10].

\begin{align*}
\text{int} \Lambda(R) \cap M_h &= \text{int} (\Lambda(R) \cap M_h) \\
\text{bd} \Lambda(R) \cap M_h &= \text{bd} (\Lambda(R) \cap M_h) \cap M_h
\end{align*}

(see Lemma 6.4 [10]). For a deck transformation $\vartheta$, from definitions we easily obtain

\begin{align*}
\vartheta(\Lambda(R)) &= \Lambda(\vartheta(R)) \\
\vartheta(\delta_\infty \Lambda(R)) &= \delta_\infty \Lambda(\vartheta(R)) \\
\vartheta(\Lambda_1(R)) &= \Lambda_1(\vartheta(R)) \\
\text{int} \vartheta(\Lambda(R)) \cap M_h &= \vartheta(\text{int} \Lambda(R)) \cap M_h = \vartheta(\text{int} \Lambda(R) \cap M_h) \\
\text{bd} \vartheta(\Lambda(R)) \cap M_h &= \vartheta(\text{bd} \Lambda(R)) \cap M_h = \vartheta(\text{bd} \Lambda(R) \cap M_h).
\end{align*}

The sets $\Lambda(R)$ and $\Lambda_1(R)$ are path-connected. $\delta_\infty \Lambda(R)$ is an open $(n - 1)$-manifold. Since Theorem 5.4 shows that for two overlapping $n$-crescents $R_1$ and $R_2$, $\alpha_{R_2}$ and $\alpha_{R_1}$ extend each other into a larger $(n - 1)$-manifold, there exists a unique great sphere $S^{n-1}$ including $\text{dev}(\delta_\infty \Lambda(R))$ and by Corollary 5.8, a unique component $A_R$
of $S^n - S^{n-1}$ such that $\text{dev}(\Lambda(R)) \subset \text{Cl}(A_R)$ and $\text{dev}(\Lambda(R) - \text{Cl}(\delta_\infty \Lambda(R))) \subset A_R$. For a deck transformation $\vartheta$ acting on $\Lambda(R)$, $A_R$ is $h(\vartheta)$-invariant. $\Lambda_1(R)$ admits a real projective structure as a manifold with totally geodesic boundary $\delta_\infty \Lambda(R)$.

**Proposition 7.2.** — $\Lambda(R) \cap M_h$ is a closed subset of $M_h$.

**Proof.** — Lemma 9.2 implies this proposition.

**Lemma 7.3.** — $\text{bd}(\Lambda(R)) \cap M_h$ is a properly imbedded topological submanifold of $M_h^o$, and $\Lambda(R) \cap M_h$ is a real projective submanifold of $M_h$ with concave boundary $\text{bd}(\Lambda(R)) \cap M_h$.

**Proof.** — Let $r$ be a point of $\text{bd}(\Lambda(R)) \cap M_h$. Since $\Lambda(R)$ is closed, $r$ is a point of a crescent $R'$ equivalent to $R$. If $r$ is a point of $\delta M_h$, then Lemma 6.1 implies that $r \in \text{int} R'$ and $r \in \text{int} \Lambda(R)$, a contradiction. Thus, $\text{bd}(\Lambda(R)) \cap M_h \subset M_h^o$.

Let $B(r)$ be an open tiny ball of $r$. Since by Lemma 6.1, $\text{bd}(\Lambda(R)) \cap M_h$ is a subset of $M_h^o$, $B(r)^o$ is an open neighborhood of $r$. Since $B(r)^o \cap \Lambda(R)$ is a closed subset of $B(r)^o$, $O = B(r)^o - \Lambda(R)$ is an open subset.

We claim that $O$ is a convex subset of $B(r)^o$. Let $x, y \in O$. Then let $s$ be the segment in $B(r)$ of $d$-length $\leq \pi$ connecting $x$ and $y$. If $s^o \cap \Lambda(R) \neq \emptyset$, then a point $z$ of $s^o$ belongs to an $n$-crescent $S$, $S \sim R$. If $z$ belongs to $S^o$, since $s$ must leave $S$, $s$ meets $\nu_S$ and is transversal to $\nu_S$ at the intersection point. Since a maximal line in the bihedron $S$ transversal to $\nu_S$ have an endpoint in $\alpha_S$, at least one endpoint of $s$ belongs to $S^o$, which is a contradiction. If $z$ belongs to $\nu_S$ and $s$ is transversal to $\nu_S$ at $z$, the same argument gives us a contradiction. If $z$ belongs to $\nu_S$ and $s$ is tangential to $\nu_S$ at $z$, then $s$ is included in the component of $\nu_S \cap M_h$ containing $z$ since $s \subset M_h$ is connected. Since $x$ and $y$ belong to $O$, this is a contradiction. Hence $s \subset O$, and $O$ is convex.

![Figure 7.1. Figures of $\Lambda(R)$](image)
Since $O$ is convex and open, $\partial O$ in $M_h$ is homeomorphic to an $(n-1)$-sphere by Proposition 2.6. As the boundary $\partial B(r)^o$ of $O$ relative to $B(r)^o = \partial B(r)^o \cap B(r)^o$, $\partial B(r)^o$ is an imbedded open $(n-1)$-submanifold of $B(r)^o$. While we have $\partial \Lambda(R) \cap B(r)^o = \partial B(r)^o$, $\partial \Lambda(R) \cap M_h$ is an imbedded $(n-1)$-submanifold. 

![Figure 7.2. A pre-two-faced submanifold.](image)

Using the same argument as in Section 6.2 of [10] (see Lemma 6.4 of [10]), we obtain the following lemma:

**Lemma 7.4.** — If $\operatorname{int} \Lambda(R) \cap M_h \cap \Lambda(S) \neq \emptyset$ for an $n$-crescent $S$, then we have $\Lambda(R) = \Lambda(S)$. Moreover, if for a crescent $S$, $\Lambda(R) \cap M_h$ and $\Lambda(S) \cap M_h$ meet and they are distinct, then $\Lambda(R) \cap \Lambda(S) \cap M_h$ is a subset of $\partial \Lambda(R) \cap M_h$ and $\partial \Lambda(S) \cap M_h$.

**Proof.** — If $\operatorname{int} (\Lambda(R) \cap M_h) \cap \Lambda(S) \neq \emptyset$ for an $n$-crescent $S$, then an $n$-crescent $T$, $T \sim S$, intersects $\operatorname{int} B(x)$ for $B(x) \subset \operatorname{int} \Lambda(R) \cap M_h$ where $B(x)$ is a tiny ball of a point $x$ of $\partial \Lambda(R) \cap M_h$.

If $B(x)$ is not a subset of $T$, then a component of $B(x) - a$ for an $(n-1)$-ball $a$, $a = \nu_T \cap B(x)$, with $\partial a \subset \partial B(x)$ is a subset of $T^o$ by Lemma 3.13. Thus, whether $B(x)$ is a subset of $T$ or not, a point $y$ of $\operatorname{int} B(x)$ lies in $T^o$. Since $y$ belongs to $T^o$ for some $T^o \sim R$, it follows that $T^o$ and $T$ overlap and hence $R \sim S$; therefore, $\Lambda(R) = \Lambda(S)$.

The second part follows easily from the first part. 

\[\square\]
Assume now that \( \Lambda(R) \) and \( \Lambda(S) \) are distinct but meet each other; \( R \) and \( S \) are not equivalent. Let \( x \) be a common point of \( \partial \Lambda(R) \) and \( \partial \Lambda(S) \), and \( B(x) \) a tiny-ball neighborhood of \( x \). By Lemma 7.3, \( x \in M_h^c \) and so \( x \in B(x)^{o} \). Let \( T \) be a crescent equivalent to \( R \) containing \( x \), and \( T' \) that equivalent to \( S \) containing \( x \). Then \( T \cap \partial R \) is the closure of a component \( A \) of \( B(x) - P \) for a totally geodesic \((n-1)\)-ball \( P \) in \( \partial B(x) \) by Lemma 3.13. Moreover, \( \nu_T \cap \partial B(x) = P \) and \( T' \cap \partial B(x) = A \), and \( A \) is a subset of \( \partial \Lambda(R) \). Let \( B \) be a neighborhood of \( \partial \Lambda(R) \).

Similarly, \( T' \cap B(x) \) is the closure of a component \( A' \) of \( B(x) - P' \) for a totally geodesic \((n-1)\)-ball \( P' \), \( \nu_T \cap B(x) = P \) with boundary in \( \partial B(x) \), and \( A' \) is a subset of \( T' \cap \partial \Lambda(S) \). Since we have

\[
T' \cap B(x) \text{ and } T' \cap B(x) \text{ are disjoint. Since } P \text{ and } P' \text{ contains } x, \text{ it follows that } P = P' \text{ and } B = A'; \text{ that is, } P \text{ and } P' \text{ are tangential. (We have that } P = P' = \nu_T \cap B(x) = \nu_T \cap B(x). \)

Since \( B \) is a subset of \( \partial \Lambda(S) \), \( B \) contains no point of \( \Lambda(R) \) by Lemma 7.4, and similarly \( A \) contains no point of \( \Lambda(S) \). Thus, \( \Lambda(R) \cap B(x) \) is a subset of the closure of \( A \), and \( \Lambda(S) \cap B(x) \) is that of \( B \). Since \( A \subset \partial \Lambda(R) \) and \( B \subset \partial \Lambda(S) \), it follows that

\[
\begin{align*}
A &= \partial \Lambda(R) \cap B(x), & B &= \partial \Lambda(S) \cap B(x), \\
P \cup A &= \Lambda(R) \cap B(x), & P \cup B &= \Lambda(S) \cap B(x), \\
P &= \partial \Lambda(R) \cap B(x) = \partial \Lambda(S) \cap B(x).
\end{align*}
\]

Hence, we have \( P = \partial \Lambda(R) \cap \partial \Lambda(S) \cap B(x) \) and \( P \) is a totally geodesic \((n-1)\)-ball with boundary in \( \partial B(x) \) and our point \( x \) belongs to \( P^o \), to begin with. Since this holds for an arbitrary choice of a common point \( x \) of \( \partial \Lambda(R) \) and \( \partial \Lambda(S) \), a tiny ball \( B(x) \) of \( x \), it follows that \( \partial \Lambda(R) \cap \partial \Lambda(S) \cap M_h = \) an imbedded totally geodesic open \((n-1)\)-submanifold in \( M_h^c \). It is properly imbedded since \( B(x) \cap \partial \Lambda(R) \cap \partial \Lambda(S) \) is compact for every choice of \( B(x) \).

The above paragraph also shows that \( \partial \Lambda(R) \cap \partial \Lambda(S) \) is an open and closed subset of \( \partial \Lambda(R) \cap M_h \). Therefore, for components \( B \) of \( \partial \Lambda(R) \cap M_h \) and \( B' \) of \( \partial \Lambda(S) \cap M_h \) where \( R \neq S \), either we have \( B = B' \) or \( B \) and \( B' \) are disjoint. If \( B = B' \), the above paragraph shows that \( B \) is a properly imbedded totally geodesic \((n-1)\)-submanifold of \( M_h \).

We say that a component of \( \partial \Lambda(R) \cap M_h \) is copied if it equals a component of \( \partial \Lambda(S) \cap M_h \) for some \( n \)-crescent \( S \) not equivalent to \( R \). Let \( c_R \) be the union of all copied components of \( \partial \Lambda(R) \cap M_h \).

**Lemma 7.5.** — Each component of \( c_R \) is a properly imbedded totally geodesic \((n - 1)\)-manifold, and equals a component of \( \nu_T \cap M_h \) for fixed \( T \), \( T \sim R \) and that of \( \nu_T \cap M_h \) for fixed \( T' \), \( T' \sim S \), where \( S \) is not equivalent to \( R \).

**Proof.** — From above arguments, we see that given \( x \) in a component \( C \) of \( c_R \), and a tiny ball \( B(x) \) of \( x \), there exists a totally geodesic \((n - 1)\)-ball \( P \) with \( \partial P \subset \partial B(x) \) so that a component of \( B(x) - P \) is included in \( T, T \sim R \) and the other component in \( T' \) for \( T' \) equivalent to \( S \) but not equivalent to \( R \).
Since $P$ is connected, $P \subset C$. Let $y$ be another point of $C$ connected to $x$ by a path $\gamma$ in $C$, a subset of $M_h$. Then we can cover $\gamma$ by a finitely many tiny balls. By induction on the number of tiny balls, we see that $y$ belongs to $\nu_T \cap M_h$ and $\nu_T \cap M_h$ for fixed $T$ and $T'$.

Let $A$ denote $\bigcup_{R \in B} c_R$ where $B$ denotes the set of representatives of the equivalence classes of bihedral $n$-crescents in $M_h$. $A$ is said to be the pre-two-faced submanifold arising from bihedral $n$-crescents. $A$ is a union of path-components that are totally geodesic $(n-1)$-manifolds closed in $M^g$.

**Proposition 7.6.** — Suppose that $A$ is not empty. Then $A$ is a properly imbedded submanifold of $M_h$ and $p|A$ is a covering map onto a closed totally geodesic imbedded $(n-1)$-dimensional submanifold in $M^g$.

**Proof.** — We follow the argument in Chapter 6 somewhat repetitively. Every pair of two components $a$ of $c_R$ and $b$ of $c_S$ for $n$-crecents $R$ and $S$ where $R, S \in B$, are either disjoint or identical. Hence, $A$ is a union of disjoint closed path-components that are some components of $c_R$ for $R \in B$. This is proved exactly as in Chapter 6.

Second, given a tiny ball $B(x)$ of a point $x$ of $M_h$, no more than one path-component of $A$ may intersect $\text{int} B(x)$. Let $a$ be a component of $c_R$ intersecting $\text{int} B(x)$. By Lemma 7.5, $a$ is a component of $\nu_S \cap M_h$ for $S \sim R$ and that of $\nu_T \cap M_h$ for $T$ not equivalent to $S$. Furthermore, $\nu_S \cap B(x)$ is a compact convex $(n-1)$-ball with boundary in $\text{bd} B(x)$. Since it is connected, $a \cap B(x) = \nu_S \cap B(x)$, and $B(x) \cap S$ is the closure of a component $C_1$ of $B(x) - (a \cap B(x))$. Similarly, $a \cap B(x) = \nu_T \cap B(x)$, and $B(x) \cap T$ is the closure of the other component $C_2$ of $B(x) - (a \cap B(x))$ for an $n$-crescent $T$ not equivalent to $R$. Since $S$ and $T$ do not overlap, it follows that $C_1$ and $C_2$ are the two disjoint components of $B(x) - (a \cap B(x))$.

Suppose that $b$ is a component of $c_U$ for $U \in B$ intersecting $\text{int} B(x)$ also. By Lemma 7.5, $b$ is a component of $\nu_T \cap M_h$ for $T \sim U$. If the $(n-1)$-ball $b \cap B(x)$ intersects $C_1$ or $C_2$, then $U \sim S$ or $U \sim T$ and $\Lambda(U) = \Lambda(R)$ or $\Lambda(U) = \Lambda(T)$ by Lemma 7.4, implying that $a = b$. If we have $b \cap B(x) \subset a \cap B(x)$, then $T'$ overlaps with at least one of $S$ or $T$, and $a = b$ as above.

Since given a tiny ball $B(x)$ no more than one distinct path-component of $A$ may intersect $\text{int} B(x)$, $A$ is a properly imbedded closed submanifold of $M^g$. The rest of the proof of proposition is the same as that of Proposition 6.4.

**Definition 7.7.** — $p(A)$ for the union $A$ of all copied components of $\Lambda(R)$ for bihedral $n$-crescents $R$ in $M_h$ is said to be the two-faced submanifold of $M$ arising from bihedral $n$-crescents (or type II).

Each component of $p(A)$ is covered by a component of $A$, i.e., a component of $\nu_R \cap M_h$ for some bihedral $n$-crescent $R$. Hence, each component of $p(A)$ is covered by open domains in $\mathbb{R}^n$ as in Chapter 6 and as we said in the introduction.

We end with the following observation:

**Proposition 7.8.** — Suppose $M_h \text{ includes no hemispheric } n \text{-crescents and } A = \bigcup_{R \in B} c_R$. Then $A$ is disjoint from $R^o$ for each $n$-crescent $R$. 

Proof. — The proof is same as that of Proposition 6.6.

Example 7.9. — Finally, we give an example in dimension 2. Let \( \vartheta \) be the projective automorphism of \( S^2 \) induced by the diagonal matrix with entries 2, 1, and 1/2. Then \( \vartheta \) has fixed points \([\pm 1, 0, 0], [0, \pm 1, 0], \) and \([0, 0, \pm 1]\) corresponding to eigenvalues \( 2, 1, 1/2 \). Given three points \( x, y, z \) of \( S^2 \), we let \( \overline{xyz} \) denote the segment with endpoints \( x \) and \( z \) passing through \( y \) if there exists such a segment. If \( x \) and \( y \) are not antipodal, then let \( \overline{xy} \) denote the unique minor segment with endpoints \( x \) and \( y \). We look at the closed lune \( B_1 \) bounded by \([0,0,1][1,0,0][0,0,-1]\) and \([0,0,1][1,0,0][0,0,-1]\), which are to be denoted by \( l_1 \) and \( l_2 \) respectively, and the closed lune \( B_2 \) bounded by \([1,0,0][0,-1,0][-1,0,0]\) and \([1,0,0][0,0,1][-1,0,0]\), which are denoted by \( l_3 \) and \( l_4 \) respectively.

We consider the domain \( U \) given by \( U = B_1 \cup B_2 \cup l_1 \cup l_2 - \{(1,0,0), (0,0,1)\} \). Since there exists a compact fundamental domain of the action of \( \langle \vartheta \rangle \), \( U/\langle \vartheta \rangle \) is a compact annulus \( A \) with totally geodesic boundary. \( U \) is the holonomy cover of \( A \). The Kuiper completion of \( U \) can be identified with \( B_1 \cup B_2 \). It is easy to see that \( B_1 \) is a 2-crescent with \( \alpha_{B_1} = l_2 \) and \( \nu_{B_1} = l_1 \) and \( B_2 \) one with \( \alpha_{B_2} = l_3 \) and \( \nu_{B_2} = l_4 \). Also, any other crescent is a subset of \( B_1 \) or \( B_2 \). Hence \( \Lambda(B_1) = B_1 \) and \( \Lambda(B_2) = B_2 \) and the pre-two-faced submanifold \( L \) equals \( [1,0,0][0,0,1] \). \( L \) covers a simple closed curve in \( A \) given by \( [1,0,0][0,0,1] /\langle \vartheta \rangle \).
CHAPTER 8

THE PRESERVATION OF CRESCENTS AFTER DECOMPOSING AND SPLITTING

In this chapter, we consider somewhat technical questions: What become of the \( n \)-crescents in the completions of the holonomy cover of a submanifold in those of the holonomy cover of an ambient manifold? What happen to \( n \)-crescents in the completion of a manifold when we split the manifold along the two-faced manifolds. The answer will be that they are preserved in the best possible sense: Propositions 8.3, 8.7, and 8.10. In the process, we will define splitting manifolds precisely and show how to construct holonomy covers of split manifolds.

Also, from this chapter, covering spaces need not be connected, which only complicates the matter of identifying the fundamental groups with the deck transformation groups. Even for disconnected spaces we can define projective completions as long as immersions to \( S^n \), i.e., developing maps, are defined since we can always pull-back the metrics in that case.

For an alternative and more intuitive approach due to the referee to proving the materials here, see Remarks 8.4 and 8.12.

Let \( M \) be a real projective manifold with empty or totally geodesic boundary; let \( M_h \) be the holonomy cover of \( M \) with development pair \((\text{dev}, h)\) and the group of deck transformations \( G_M \); let \( p : M_h \to M \) denote the covering map. Let \( N \) be a connected submanifold of \( M \) of codimension 0 with an induced real projective structure. Then \( p^{-1}(N) \) is a codimension 0 submanifold of \( M_h \). Choose a component \( A \) of \( p^{-1}(N) \). Then \( A \) is a submanifold in \( M_h \) and \( p|_A \) covers \( N \) with the deck transformation group \( G_A \) equal to the group of deck transformations of \( M_h \) preserving \( A \).

We claim that \( A \) is a holonomy cover of \( N \) with development pair \((\text{dev}|_A, h')\) where \( h' \) is a composition of the inclusion homomorphism and \( h : G_M \to \text{Aut}(S^n) \). First, for each closed path in \( N \) which lifts to one in \( A \) obviously has a trivial holonomy (see Section 8.4 in [28]). Given a closed path in \( N \) with a trivial holonomy, it lifts to a closed path in \( M_h \) with a base point in \( A \). Since \( A \) is a component of \( p^{-1}(N) \), it follows that the closed path is in \( A \). Therefore, \( A \) is the holonomy cover of \( N \).

**Lemma 8.1.** — Let \( A \) be a component of \( p^{-1}(N) \) in \( M_h \) of a submanifold \( N \) of \( M \). Then \( A \) is a holonomy cover of \( N \) with developing map \( \text{dev}|_A \). \( \square \)
Let us discuss about the Kuiper completion of $A$. The path-metric on $A$ is induced from the Riemannian metric on $A$ induced from $S^n$ by $\text{dev}|A$. The completion of $A$ with respect to the metric is denoted by $A_\infty$; that is, $A_\infty = A - A$.

Note that $A$ may not necessarily equal the closure of $A$ in $M_h$. A good example is the complement of the closure of the positive axis in $\mathbb{R}^2$ as $A$ and $\mathbb{R}^2$ as $M_h$.

Let $i : A \to M_h$ be an inclusion map. Then $i$ extends to a distance-decreasing map $i : \overline{A} \to \text{Cl}(A) \subset M_h$.

**Lemma 8.2**

(i) $i^{-1}(M_{h,\infty})$ is a subset of $A_{\infty}$.

(ii) If $A$ is closed as a subset of $M_h$, then $i(A_{\infty}) \subset M_{h,\infty}$. Thus, in this case, $i^{-1}(M_{h,\infty}) = A_{\infty}$.

(iii) Let $P$ be a submanifold in $A$ with convex interior $P^o$. Then the closure $P'$ of $P$ in $A$ maps isometric to the closure $P'^o$ of $P$ in $M_h$ under $i$. Here $P'$ and $P'^o$ are homeomorphic.

(iv) $i$ maps $P' \cap A_{\infty}$ homeomorphic onto $P'^o \cap M_{h,\infty}$.

**Proof.** — (i) If $x$ is a point of $i^{-1}(M_{h,\infty})$, then $x$ does not belong to $A$ since otherwise $i(x) = i_y(x) \in M_h$.

(ii) Suppose not. Then there exists a point $x$ in $M_h$ such that $x = i(y)$ for $y \in A_{\infty}$. There exists a sequence of points $y_i \in A$ with unique limit point $y$ with respect to the path-metric $d_A$ on $A$ induced by $\mu$, and hence, $y_i \to y$ with respect to $d$ also. The sequence of points $i(y_i) = y_i \in A$ converges $x$ since $i$ is distance-decreasing. Therefore we obtain $y = x$ and $y \in A$, a contradiction.

(iii) Since $i|P^o$ is an isometry with respect to $d_A$ and $d$ on $M_h$, the third part follows.

(iv) By (i), the inverse image of $P'^o \cap M_{h,\infty}$ under $i|P'$ is a subset of $A_{\infty}$. By (ii), we see $i(P' \cap A_{\infty}) \subset P'^o \cap M_{h,\infty}$. 

Suppose that $A$ is a closed subset of $M_h$. Let $R$ be an $n$-crescent in $M_h$, and consider a submanifold $R' = R \cap M_h$ with convex interior $R^o$. If $R'$ is a subset of a submanifold $A$ of $M_h$, then the above lemma shows that the closure $R'^o$ of $R'$ in $A$ is isometric to $R$ under $i$. By the above lemma, we obtain that $R'^o$ is also a crescent with $\alpha_i = i^{-1}(\alpha_i)$, and $\nu_i = i^{-1}(\nu_i)$. Moreover, if $R$ is bihedral (resp. hemispheric), then $R'^o$ is bihedral (resp. hemispheric).

Conversely, let $R$ be an $n$-crescent in $A$. By Lemma 8.2, $iR : R \to i(R)$ is an imbedding, and the closure of $i(R \cap A)$ equals $i(R)$ and is a convex $n$-ball. By Lemma 8.2, $i(R)$ is an $n$-crescent, which is bihedral (resp. hemispheric) if $R$ is bihedral (resp. hemispheric) since $\alpha_i = i(\alpha_i)$ and $\nu_i = i(\nu_i)$ hold.

Thus, we have proved.

**Proposition 8.3** — Let $A$ be a submanifold of $M_h$ closed as a subset of $M_h$. There exists a one to one correspondence of all bihedral $n$-crecents in $A$ and those in $\text{Cl}(A)$ in $M_h$ given by $R \leftrightarrow R'$ for a bihedral $n$-crescent $R$ in $A$ and $R'$ one in $\text{Cl}(A)$ if and only if $R^o = R'^o$. The same statement holds for hemispherical $n$-crecents.
Remark 8.4. — An alternative proof suggested by the referee is as follows: If \( R \) is a \( n \)-crescent in \( A \), then \( R \cap M_h \) is an \( n \)-crescent set. By Remark 3.8, the closure of \( R \) in \( M_h \) is a crescent. Conversely, given a crescent \( R \) in \( \text{Cl}(A) \), as \( R \cap M_h \) is an \( n \)-crescent set in \( M_h \), \( R \cap M_h \) is an \( n \)-crescent set in \( A \). Thus the closure of \( R \cap M_h \) is an \( n \)-crescent in \( A \).

We give a precise definition of splitting. Let \( N \) be a real projective \( n \)-manifold with a properly imbedded \((n-1)\)-submanifold \( A \). We take an open regular neighborhood \( N \) of \( A \), which is an \( I \)-bundle over \( A \). Let us enumerate components of \( A \) by \( A_1, \ldots, A_n, \ldots \) and corresponding components of \( N \) by \( N_1, \ldots, N_n, \ldots \), which are regular neighborhoods of \( A_1, \ldots, A_n, \ldots \) respectively. (We do not require the number of components to be finite.)

For an \( i \), \( N_i \) is an \( I \)-bundle over \( A_i \). By parameterizing each fiber by a real line, \( N_i \) becomes a vector bundle over \( A \) with a flat linear connection. We see that there is a subgroup \( G_i \) of index at most two in \( \pi_1(A_i) \) with trivial holonomy. The single or double cover \( \tilde{N}_i \) of \( N_i \) corresponding to \( G_i \) is a product \( I \)-bundle over \( \tilde{A}_i \) the cover of \( A_i \) corresponding to \( G_i \), considered as a submanifold of \( \tilde{N}_i \).

Since \( N_i \) is a product or twisted \( I \)-bundle over \( A_i \), \( N_i - A_i \) has one or two components. If \( N_i - A_i \) has two components, then we take the closure of each components in \( N_i \) and take their disjoint union \( \bar{N}_i \) which has a natural inclusion map \( \iota_i : N_i - A_i \to \bar{N}_i \). If \( N_i - A_i \) has one component, then take the double cover \( \tilde{N}_i \) of \( N_i \) so that \( \tilde{N}_i \) is now a product \( I \)-bundle over \( \tilde{A}_i \). Then \( N_i - A_i \) lifts and imbeds onto a component of \( \tilde{N}_i - \tilde{A}_i \). We denote by \( \bar{N}_i \) the closure of this component in \( \tilde{N}_i \). There is a natural lift \( \iota_i : N_i - A_i \to \bar{N}_i \), which is an imbedding. After we do this for each \( i, i = 1, \ldots, n \), we identify \( N - A \) and the disjoint union \( \bigsqcup_{i=1}^n \bar{N}_i \) of all \( N_i \) by the maps \( \iota_i \). When \( A \) is not empty, the resulting manifold \( M \) is said to be the split manifold obtained from \( N \) along \( A \) (this is just for terminological convenience).

We see that for each component of \( A \), we get either two copies or a double cover of the component of \( A \) in the boundary of the split manifold \( M \) which are newly created by splitting. There is a natural quotient map \( q : M \to N \) by identifying these new faces to \( A \), i.e., \( q[q^{-1}(A)] : q^{-1}(A) \to A \) is a two-to-one covering map. Therefore, it is easy to see that \( M \) is compact if \( N \) is compact and \( M \) has totally geodesic boundary if \( A \) is totally geodesic.

Let \( N_h \) be a holonomy cover of \( N \) with a development pair \((\text{dev}, h)\). We let \( G_N \) be the group of deck transformations of the covering map \( p : N_h \to N \). If one splits \( N_h \) along the properly imbedded submanifold \( p^{-1}(A) \), then it is easy to see that the split manifold \( M' \) covers the manifold \( M \) of \( N \) split along \( A \) with covering map \( p' \) obtained from extending \( p \). However, \( M' \) may not be connected; for each component \( M_i \) of \( M \), we choose a component \( M_i' \) of \( M' \) covering that component. \( M_i \) includes exactly one component \( P_i \) of \( N - A \), and \( M_i' \) includes exactly one component \( P_i' \) of \( N_h - p^{-1}(A) \) as a dense open subset. Thus, \( \bigsqcup_{i=1}^n P_i' \) covers \( \bigsqcup_{i=1}^n P_i \) and \( \bigsqcup_{i=1}^n M_i' \) covers \( M \).

Remark 8.5. — The submanifold \( p^{-1}(A) \) is orientable since great \( (n-1) \)-spheres in \( S^n \) are orientable and \( \text{dev} \) maps each components of \( p^{-1}(A) \) into great \( (n-1) \)-spheres
as immersions. Thus, there are no twisted 1-bundle neighborhoods of components of \(p^{-1}(A)\) as \(N_h\) is orientable also.

Let \(G_i\) be the subgroup of deck transformations of \(N_h\) acting on \(P_i^\prime\), which is the group of deck transformations of the covering map \(p|P_i^\prime : P_i^\prime \to P_i\). For each \(i\), we define the homomorphism \(h_i : G_i \to \text{Aut}(S^n)\) by \(h \circ l_i\) where \(l_i : G_i \to G_N\) is the homomorphism induced from the inclusion map. Since \(P_i^\prime\) covers a component \(P_i\) of \(N - A\), Lemma 8.1 shows that \(P_i^\prime\) is a holonomy cover of that component with the development pair \((\text{dev}|P_i^\prime, h_i)\).

The developing map \(\text{dev}|P_i\) uniquely extends to a map from \(M_i^\prime\) as an immersion for each \(i\); we denote by \(\text{dev}^\prime : \prod_{i=1}^n M_i^\prime \to S^n\) the map obtained this way. It is easy to see that the action of \(G_i\) naturally extends to one on \(M_i^\prime\) and becomes the group of deck transformations of the covering map \(p|M_i^\prime : M_i^\prime \to M_i\). Since \(M_i^\prime\) obtained from \(P_i^\prime\) by attaching boundary, it follows that \(M_i^\prime\) is the holonomy cover of \(M_i\) with development pair \((\text{dev}^\prime|M_i^\prime, h_i)\). We say that the disjoint union \(\prod_{i=1}^n M_i^\prime\) is a holonomy cover of \(M = \prod_{i=1}^n M_i\).

Suppose that there exists a nonempty pre-two-faced submanifold \(A\) of \(N_h\) arising from hemispheric \(n\)-crescents. Then we can split \(N\) by \(p(A)\) to obtain \(M\) and \(N_h\) by \(A\) to obtain \(M^\prime\), and \(M^\prime\) covers \(M\) under the extension \(\tilde{p}\) of the covering map \(p : N_h \to N\).

We claim that the collection of hemispheric \(n\)-crescents in \(N_h\) and the completion \(M^\prime\) of \(M^\prime\) are in one to one correspondence. Let \(q : M^\prime \to N_h\) denote the natural quotient map identifying the newly created boundary components which restricts to the inclusion map \(N_h - A \to N_h\). We denote by \(A^\prime\) the set \(q^{-1}(A)\), which are newly created boundary components of \(M^\prime\). Let \(M^\prime\) denote the projective completion of \(M^\prime\) with the metric \(d^\prime\) extended from \(N_h - A\). Then as \(q\) is distance-decreasing, \(q\) extends to a map \(\tilde{q} : M^\prime \to N_h\) which is one-to-one and onto on \(M^\prime - A^\prime \to N_h - A\).

**Lemma 8.6.** — \(q\) maps \(A^\prime\) to \(A\), \(M^\prime\) to \(N_h\), and \(M^\prime_{\infty}\) to \(N_{h,\infty}\). (Which implies that \(q^{-1}(A) = A^\prime\), \(q^{-1}(N_h) = M^\prime\), and \(q^{-1}(N_{h,\infty}) = M_{\infty}\).)

**Proof.** — The result of this lemma is essentially a consequence of the properness of the map \(q\). We obviously have \(q(A^\prime) = q(A^\prime) = A\) and \(q(M^\prime) = q(M^\prime) = N_h\).

If a point \(x\) of \(M^\prime\) is mapped to that of \(A\), then let \(\gamma\) be a path in \(N_h - A\) ending at \(q(x)\) in \(A\). Then we may lift \(\gamma\) to a path \(\gamma^\prime\) in \(M^\prime - A^\prime\). \(q(x)\) has a small compact neighborhood \(B\) in \(N_h\) where \(\gamma\) eventually lies in, and as the closure \(B^\prime\) of a component of \(B - A\) is compact, there exists a compact neighborhood \(B''\) in \(M^\prime\) mapping homeomorphic to \(B^\prime\) under \(q\) and \(\gamma^\prime\) eventually lies in \(B''\). This means that \(x\) lies in \(B''\) and hence in \(M^\prime\). As \(q^{-1}(A) = A^\prime\), \(x\) lies in \(A^\prime\). Thus, \(q^{-1}(A) = A^\prime\) and points of \(M^\prime_{\infty}\) cannot map to a point of \(A\).

Using a path-lifting argument, we may show that \(q(M^\prime_{\infty})\) is a subset of \(A \cup N_{h,\infty}\) as \(q(M^\prime_{\infty}) = q(M^\prime_{\infty}) = N_{h,\infty}\). Hence, this and the above paragraph show that \(q(M_{\infty}) \subset N_{h,\infty}\).

First, consider the case when \(N_h\) includes a hemispheric \(n\)-crescent \(R\). Since by Proposition 6.6, \(R^\circ\) is a subset of \(N_h - A\), \(R^\circ\) is a subset of \(M^\prime\). The closure \(R^\circ\) of
Proposition 8.7. — There exists a one-to-one correspondence between all hemispheric $n$-crecents in $N_h$ and those of $M'$ by the correspondence $R \leftrightarrow R'$ if and only if we have $R^o = R^o$. 

Corollary 8.8. — If $N_h$ includes a hemispheric $n$-crescent, then the Kuiper completion of the holonomy cover of at least one component of the split manifold $M$ along the two-faced submanifold, also includes a hemispheric $n$-crescent.

Proof. — Let $M_i$ be the components of $M$ and $M_i'$ their holonomy cover as obtained earlier in this chapter; let $P_i$ be the component of $N - p(A)$ in $M_i$ and $P_i^0$ that of $N_h - A$ in $M_i'$ so that $P_i^0$ covers $P_i$. We regard two components of $N_h - A$ to be equivalent if there exists a deck transformation of $N_h$ mapping one to the other. Then $P_i$ is a representative of an equivalence class $A_i$. As the deck transformation group is transitive in an equivalence class $A_i$, we see that given two elements $P_i^0$ and $P_i^0$ in $A_i$, the components $M_i^0$ and $M_i^0$ of $M'$ including them respectively are projectively isomorphic as the deck transformation sending $P_i^0$ to $P_i^0$ extends to a projective map $M_i^0 \to M_i^0$, and hence to a quasi-isometry $M_i^0 \to M_i^0$. Since real projective maps extending to quasi-isometries send hemispheric $n$-crecents to hemispheric $n$-crecents, if no $M_i'$ includes a hemispheric $n$-crescent, then it follows that $M'$ do not also. This contradicts Proposition 8.7.

Proposition 8.9. — If the Kuiper completions of holonomy cover of a submanifold of $N$ or a split manifold of $N$ by a properly-imbedded totally-geodesic closed submanifold in $N$ includes hemispheric $n$-crecents, then so does $N_h$.

Proof. — The first part follows from Proposition 8.3 and the second part follows from Lemma 8.6 as in the last part of the argument to prove Proposition 8.7.

Now, we suppose that $N_h$ includes no hemispheric $n$-crecents $R$ but includes some bihedral $n$-crecents. Let $A$ be the pre-two-faced submanifold of $N_h$ arising from bihedral $n$-crecents. We split $N$ by $p(A)$ to obtain $M$ and $N_h$ by $A$ to obtain $M'$, and $M'$ covers $M$ under the extension $p'$ of the covering map $p : N_h - A \to N - p(A)$.

By same reasonings as above, we obtain
Proposition 8.10. — There exists a one-to-one correspondence between all bihedral n-crescents in $N_h$ and those of $M^1$ by the correspondence $R \leftrightarrow R^0$ if and only if $R^0 = R^0$.

Corollary 8.11. — If $N_h$ includes a bihedral n-crescent, then the projective completion of the holonomy cover of at least one component of the split manifold $M$ along the two-faced submanifold, also includes a bihedral n-crescent.

Remark 8.12. — An alternative proof of Propositions 8.7 and 8.10, we use the crescent sets (see Remark 3.8). As the interior of n-crescent sets are disjoint from pre-two-faced submanifolds, if we split along the submanifolds, we see that the boundary parts of n-crescents “double” along the pre-two-faced submanifolds, and hence, the crescent sets are preserved. This intuitive argument can be made into a proof quite easily.

Lastly, we will note the relationship between covering spaces and crescents with a proof sketched. This result will not be used but for the completeness sake we include it here.

Proposition 8.13. — Let $M^1$ and $M^2$ be connected developing covers of $M$ and $M^1$ covers $M^2$ by $g$. Then hemispheric (resp. bihedral) n-crescents in the Kuiper completion $\tilde{M}^1$ of $M^1$ correspond to hemispheric (resp. bihedral) n-crescents in the Kuiper completion $\tilde{M}^2$ of $M^2$ by the number of sheets $[\pi_1(M^1) : \pi_1(M^2)]$ to one.

To begin a proof, we can choose developing maps $\text{dev}^1$ and $\text{dev}^2$ for $M^1$ and $M^2$ so that $\text{dev}^2 = \text{dev}^1 \circ g$ as in Proposition 3.4. Then we pull-back the metric $d$ to $d^1$ and $d^2$ on $M^1$ and $M^2$ respectively, and obtain completed spaces $\tilde{M}^1$ and $\tilde{M}^2$. The covering map $g$ extends to a distance-decreasing map $g' : M^1 \rightarrow M^2$.

We need to first show:

Lemma 8.14. — $g'$ maps the ideal set $\tilde{M}_\infty^1$ of $M^1$ into the ideal set $\tilde{M}_\infty^2$ of $M^2$; hence, $g^{-1}(\tilde{M}_\infty^2) = \tilde{M}_\infty^1$.

Proof. — The proof again uses a path-lifting argument and the properness of $g$. □

The next step is to show that given an n-crescent $R$ in $\tilde{M}^1$, the image $g'(R)$ is an n-crescent in $\tilde{M}^2$. This follows by the fact that $g'$ restricted to $R$ is an imbedding and the above lemma 8.14. Given an n-crescent $S$ in $\tilde{M}^2$, as $S \cap M^2$ is simply connected, there exists a set $S'$ in $\tilde{M}^1$ mapping homeomorphic to $S \cap M^2$ by $g$. We can show easily that the closure of $S'$ is an n-crescent. □
CHAPTER 9

THE CONSTRUCTION OF CONCAVE AFFINE
MANIFOLDS

In this chapter we prove Theorem 1.1 using the previous three-sections, in a more or less straightforward manner. We will start with hemispheric crescent case and then the bihedral case. The proof of the bihedral case is entirely similar but will be spelled out.

Definition 9.1. — A concave affine manifold $N$ of type I is a real projective manifold such that its holonomy cover $N_h$ is a subset of a hemispheric $n$-crescent in $N_h$. A concave affine manifold $N$ of type II is a real projective manifold with concave or totally geodesic boundary so that $N_h$ is a subset of $\Lambda(R)$ for a bihedral $n$-crescent $R$ in $N_h$ and $N_h$ includes no hemispheric $n$-crescents. We allow $N$ to have nonsmooth boundary that is concave.

It is easy to see that $N$ is a concave affine manifold of type I if and only if $N_h$ equals a hemispheric $n$-crescent.

Given a real projective manifold $N$ with a developing map $\text{dev} : N_h \to S^n$ and the holonomy homomorphism $h : \pi_1(N) \to \text{Aut}(S^n)$, suppose that $\text{dev}(N_h)$ is a subset of an open $n$-hemisphere, i.e., an affine patch, and $h(\pi_1(N))$ acts on this hemisphere. Then obviously $h(\pi_1(N))$ restricts to affine transformations of the affine patch, and $(\text{dev}, h)$ can be considered a development pair of an affine structure. Hence, $N$ admits a natural affine structure.

If $M$ is a concave affine manifold of type I, from the properties proved in the above Chapter 8, $\text{dev}(M_h)$ equals an $n$-hemisphere $H$. Since the holonomy group acts on $H$, the interior $M^o$ has a compatible affine structure. If $M$ is one of the second type, then for each bihedral $n$-crescent $R$, $\text{dev}$ maps $R \cap M_h$ into the interior of an $n$-hemisphere $H$ (see Chapter 7). Hence, it follows that $\text{dev}$ maps $M_h$ into $H^o$. Since given a deck transformation $\vartheta$, we have $\vartheta(\Lambda(R)) = \Lambda(\vartheta(R)) \supset M_h$, we obtain $\text{int}(\Lambda(\vartheta(R))) \cap \text{int}(\Lambda(R)) \cap M_h \neq \emptyset$ and $R \sim \vartheta(R)$ by Lemma 7.4. This shows that $\Lambda(R) = \Lambda(\vartheta(R)) = \vartheta(\Lambda(R))$ and $\delta_{\infty} \Lambda(R) = \delta_{\infty} \Lambda(\vartheta(R)) = \vartheta(\delta_{\infty} \Lambda(R))$ for each deck transformation $\vartheta$ by equation 7.1. Since $\text{dev}(\delta_{\infty} \Lambda(R))$ is a subset of a unique great sphere $S^{n-1}$, it follows that $h(\vartheta)$ acts on $S^{n-1}$ and since $\text{dev}(M_h)$ lies in $H^o$, the holonomy group acts on $H^o$. Therefore, $M$ has a compatible affine structure.
If $M$ is a concave affine manifold of type I, then $\delta M$ is totally geodesic since $M_h = R \cap M_h$ for an hemispheric $n$-crescent $R$ and $\delta M_h = \nu_R \cap M_h$. If $M$ is one of type II, then $\delta M$ is concave, as we said in the definition above.

Let $M$ be a compact real projective manifold with empty or totally geodesic boundary, and $p : M_h \to M$ the holonomy covering map with development pair $(\text{dev}, h)$.

For the purpose of the following lemma, we say that two $n$-crecents $S$ and $T$, hemispheric or bihedral, to be equivalent if there exists a chain of $n$-crecents $T_1, T_2, \ldots, T_n$ so that $S = T_1$ and $T = T_i$ and $T_i$ and $T_{i+1}$ overlap for each $i = 1, \ldots, n - 1$. We will use this definition in this chapter only.

**Lemma 9.2.** Let $x_i$ be a sequence of points of $M_h$ converging to a point $x$ of $M_h$, and $x_i \in R_i$ for $n$-crecents $R_i$ for each $i$. Then for any choice of an integer $N$, we have $R_i \sim R_j$ for infinitely many $i, j \geq N$. Furthermore, if each $R_i$ is an $n$-hemisphere, then $R_i = R_j$ for infinitely many $i, j \geq N$. Finally, $x$ belongs to an $n$-crescent $R$ for $R \sim R_i$ for infinitely many $i$.

**Proof.** Let $B(x)$ be a tiny ball of $x$. Assume $x_i \in \text{int} B(x)$ for each $i$. We can choose a smaller $n$-crescent $S_i$ in $R_i$ so that $x_i$ now belongs to $\nu_{S_i}$ with $\alpha_{S_i}$ included in $\alpha_{R_i}$, as $R_i$ are geometrically “simple”, i.e., a convex $n$-bihedron or an $n$-hemisphere.

Since $B(x)$ cannot be a subset of $S_i$, $S_i \cap B(x)$ is the closure of a component of $B(x) - a_i$ for $a_i = \nu_{S_i} \cap B(x)$ an $(n - 1)$-ball with boundary in $\text{bd} B(x)$. Let $v_i$ be the outer-normal vector at $x_i$ to $\nu_{S_i}$ for each $i$. Choose a subsequence $i_j$, with $i_1 = N$, of $i$ so that the sequence $v_{i_j}$ converges to a vector $v$ at $x$. Corollary 3.16 shows that there exists an $n$-crescent $R$ so that $\text{dev}(R)$ is a limit of $\text{dev}(S_{i_j})$, $R$ contains $x$, and $R$ and $S_{i_j}$ include a fixed common $n$-ball $P$ for $j$ sufficiently large. Hence, $S_{i_j}$ is equivalent to $S_{i_k}$ for $j, k$ sufficiently large. Since we have $R_{i_j} \sim S_{i_j}$ as $S_{i_j}$ is a subset of $R_{i_j}$, we obtain $R_{i_j} \sim R_{i_k}$ for $j, k$ sufficiently large.

If $R_i$ are $n$-hemispheres, then Theorem 5.1 shows that $R_{i_j} = R_{i_k}$ for $j, k$ sufficiently large. \hfill \Box

We begin the proof of the Main Theorem 1.1. Actually, what we will be proving is the following theorem, which together with Theorem 4.6 implies Theorem 1.1.

**Theorem 9.3.** Suppose that $M$ is a compact real projective $n$-manifold with totally geodesic or empty boundary, and that $M_h$ is not real projectively diffeomorphic to an open $n$-hemisphere or $n$-bihedron. Then the following statements hold:

- If $M_h$ includes a hemispheric $n$-crescent, then $M$ includes a compact concave affine $n$-submanifold $N$ of type I or $M^o$ includes the two-faced $(n-1)$-submanifold arising from hemispheric $n$-crescent.
- If $M_h$ includes a bihedral $n$-crescent, then $M$ includes a compact concave affine $n$-submanifold $N$ of type II or $M^o$ includes the two-faced $(n-1)$-submanifold arising from bihedral $n$-crescent.

Converse statements also hold.
First, we consider the case when $M_h$ includes an $n$-crescent $R$ that is an $n$-hemisphere. Suppose that there is no copied component of $\nu_T \cap M_h$ for every hemispheric $n$-crescent $T$. Recall from Chapter 6 that either $R = S$ or $R$ and $S$ are disjoint for every pair of hemispheric $n$-crescents $R$ and $S$.

Let $x \in M_h$ and $B(x)$ the tiny ball of $x$. Then only finitely many distinct hemispheric $n$-crescents intersect a compact neighborhood of $x$ in $\text{int} B(x)$. Otherwise, there exists a sequence of points $x_i$ converging to a point $y$ of $\text{int} B(x)$, where $x_i \in \text{int} B(x)$ and $x_i \in R_i$ for mutually distinct hemispheric $n$-crescents $R_i$, but Lemma 9.2 contradicts this.

Consider $R \cap M_h$ for a hemispheric $n$-crescent $R$. Since $R$ is a closed subset of $M_h$, $R \cap M_h$ is a closed subset of $M_h$. Let $A$ be the set $\bigcup_{R \in H} R \cap M_h$. Then $A$ is a closed subset of $M_h$ by above. Since $R \cap M_h$ is a submanifold for each $n$-crescent $R$, $A$ is a submanifold of $M_h$, a closed subset. Since the union of all hemispheric $n$-crescents $A$ is deck transformation group invariant, we have $p^{-1}(p(A)) = A$. Thus, $p|A$ is a covering map onto a compact submanifold $N$ in $M$, and $p|R \cap M_h$ is a covering map onto a component of $N$ for each hemispheric $n$-crescent $R$.

Since the components of $A$ are locally finite in $M_h$, it follows that $N$ has only finitely many components. Let $K$ be a component of $N$. By Lemma 8.1, $R \cap M_h$ is a holonomy cover of $K$. Let $K$ be the projective completion of $R \cap M_h$. The closure of $R \cap M_h$ in $K$ is a hemispheric $n$-crescent identical with $K$ by Proposition 8.3. Hence, $K$ is a concave affine manifold of type I.

If there is a copied component of $\nu_T \cap M_h$ for some hemispheric $n$-crescent $T$, Proposition 6.4 implies the Main theorem.

Now, we assume that $M_h$ includes only $n$-crescents that are $n$-bihedrons. Suppose that there is no copied component of $\partial \Lambda(T) \cap M_h$ for every bihedral $n$-crescents $T$, $T \in B$. Then either $\Lambda(R) = \Lambda(S)$ or $\Lambda(R)$ and $\Lambda(S)$ are disjoint for $n$-crescents $R$ and $S$, $R, S \in B$, by the results of Chapter 7.

Using this fact and Lemma 9.2, we can show similarly to the proof for the hemispheric $n$-crescent case that $A = \bigcup_{R \in B} \Lambda(R) \cap M_h$ is closed: $\Lambda(R) \cap M_h$ is a closed subset of $M_h$ by Proposition 7.2. For each point $x$ of $M_h$ and a tiny ball $B(x)$ of $x$, there are only finitely many mutually distinct $\Lambda(R_i)$ intersecting a compact neighborhood of $x$ in $\text{int} B(x)$ for $n$-crescents $R_i$. Otherwise, we get a sequence $x_i$, $x_i \in \text{int} B(x)$, converging to $y$, $y \in \text{int} B(x)$, so that $x_i \in \Lambda(R_i)$ for $n$-crescents $R_i$ with mutually distinct $\Lambda(R_i)$, i.e., $R_i$ is not equivalent to $R_j$ whenever $i \neq j$. Then $x_i \in S_i$ for an $n$-crescent $S_i$ equivalent to $R_i$. Lemma 9.2 implies $S_i \sim S_j$ for infinitely many $i, j \geq N$. Since $S_i$ is equivalent to $R_i$, this contradicts the fact that $\Lambda(R_i)$ are mutually distinct.

The subset $A$ is a submanifold since each $\Lambda(R) \cap M_h$ is one for each $R$, $R \in B$. Similarly to the hemisphere case, since $p^{-1}(p(A)) = A$, we obtain that $p|A$ is a covering map onto a compact submanifold $N$ in $M$, and $p|\Lambda(R) \cap M_h$, $R \in B$, is a covering map onto a component of $N$. $N$ has finitely many components since the components of $A$ are locally finite in $M_h$ by the above paragraph.

Let $K$ be the component of $N$ that is the image of $\Lambda(R) \cap M_h$ for $R, R \in B$. By Lemma 8.1, $\Lambda(R) \cap M_h$ is a holonomy cover of $K$. Let $K_h$ denote the projective
completion of $\Lambda(R) \cap M_h$. For each crescent $S$, $S \sim R$, the closure $S'$ of $S \cap M_h$ in $K_h$ is an $n$-crescent by Proposition 8.3. It follows that each point $x$ of $\Lambda(R) \cap M_h$ is a point of a crescent $S'$ in $K$ equivalent to the crescent $R'$, the closure of $R \cap M_h$ in $K$. Therefore, by Lemma 7.3, $N$ is a finite disjoint union of compact concave affine manifolds of type II.

When there are copied components of $\partial \Lambda(R) \cap M_h$ for some $R \in \mathcal{B}$, then Proposition 7.6 completes the proof of the Main theorem.

The converse part of the Main theorem follows by Proposition 8.3 since the Kuiper completions of concave submanifolds includes an $n$-crescents clearly. $\square$
In this chapter, we will prove Corollary 1.2. The basic tools are already covered in previous three chapters. As before, we study hemispheric case first.

Let $M$ be a compact real projective $n$-manifold with empty or totally geodesic boundary. We will assume that $M$ is not $(n-1)$-convex, and so $M_h$ is not projectively diffeomorphic to an open $n$-bihedron or an open $n$-hemisphere, so that we can apply various results in Chapters 5 to 8, such as the intersection properties of hemispheric and bihedral $n$-crescents. We will carry out various decomposition of $M$ in this chapter. Since in each of the following steps, the results are real projective manifolds with nonempty boundary if nontrivial decomposition had occurred, it follows that their holonomy covers are not projectively diffeomorphic to open $n$-bihedrons and open $n$-hemispheres. So our theory in Chapters 5 to 9 continues to be applicable.

We show a diagram of manifolds that we will be obtaining in the construction. The ladder in the first row is continued to the next one. Consider them as one continuous ladder.

\[
\begin{align*}
M & \Rightarrow_{p(A_1)} M^s \Rightarrow N \coprod K \Rightarrow_{p(A_2)} \\
M_h & \Rightarrow_{A_1} M^s_h \Rightarrow N_h \coprod \bigcup_{R \in \mathcal{H}} \{ R \cap N_h \} \Rightarrow_{A_2} \\
N^s_h \coprod K & \Rightarrow S \coprod T \coprod K \\
N_h^s \coprod \bigcup_{R \in \mathcal{H}} R \cap N_h & \Rightarrow S_h \coprod \bigcup_{R \in \mathcal{H}} \Lambda(R) \cap N_h^s \coprod \bigcup_{R \in \mathcal{H}} R \cap N_h
\end{align*}
\]  

(10.1)

where the notation $\Rightarrow_A$ means to split along a submanifold $A$ if $A$ is compact and means to split and take appropriate components to obtain a holonomy cover if $A$ is noncompact, $\Rightarrow$ means to decompose and to take appropriate components, $\coprod$ means a disjoint union and other symbols will be explained as we go along. When any of $A_1, K, A_2, T$ is empty, then the operation of splitting or decomposition does not take place and the next manifolds are identical with the previous ones. For convenience, we will assume that all of them are not empty in the proof.

To begin, suppose that $M$ is not $(n-1)$-convex, and we will now be decomposing $M$ into various canonical pieces. Let $p : M_h \to M$ denote the holonomy covering
map with development pair \((\text{dev}, h)\). (Note that the covering maps in the spaces constructed below will be all denoted by \(p\). Since the domains of definition are different this causes no confusion.)

Since \(M\) is not \((n-1)\)-convex, \(M_h\) includes an \(n\)-crescent (see Theorem 4.6). By Theorem 9.3, \(M\) has a two-faced \((n-1)\)-manifold \(S\), or \(M\) includes a concave affine manifold.

Suppose that \(M_h\) has a hemispheric \(n\)-crescent, and that \(A_1\) is a pre-two-faced submanifold arising from hemispheric \(n\)-crescents. (As before \(A_1\) is two-sided.) Let \(M^s\) denote the result of the splitting of \(M\) along \(p(A_1)\), and \(M^t\) that of \(M_h\) along \(A_1\), and \(A_1^t\) the boundary of \(M^t\) corresponding to \(A_1\), “newly created from splitting.” We know from Chapter 7 that there exists a holonomy cover \(M_h^s\) of \(M^s\) that is a disjoint union of suitable components of \(M^t\). This completes the construction of the first column of arrows in equation 10.1.

We now show that \(M^s\) now has no two-faced submanifold of type I. Let \(M^t\) denote the projective completion of \(M^t\). Suppose that two hemispheric \(n\)-crescents \(R\) and \(S\) in \(M^t\) meet at a common component \(C\) of \(\nu_R \cap M^t\) and \(\nu_S \cap M^t\) and that \(R\) and \(S\) are not equivalent. Proposition 6.4 applied to \(M^t\) shows that \(C \subset M^{t,0}\); in particular, \(C\) is disjoint from \(A_1\).

Recall the map \(\hat{q}: M^t \rightarrow M_h\) extending the quotient map \(q: M^t \rightarrow M_h\) identifying newly created split faces in \(M^t\). There exist hemispheric \(n\)-crescents \(\hat{q}(R)\) and \(\hat{q}(S)\) in \(M_h\) with same interior as \(R^s\) and \(S^s\) included in \(M_h - A_1\) by Proposition 8.7.

Since \(\nu_R \cap \nu_S \cap M^t\) belongs to \(M^t - A_1^t = M_h - A_1\), it follows that \(q(\nu_R)\) and \(q(\nu_S)\) meet in \(M_h - A_1\). Since obviously \(\hat{q}(\nu_R) \subset \hat{q}(R)\) and \(\hat{q}(\nu_S) \subset \hat{q}(S)\), we have that \(\hat{q}(R)\) and \(\hat{q}(S)\) meet in \(M_h - A_1\). However, since \(\hat{q}(R)\) and \(\hat{q}(S)\) are hemispheric \(n\)-crescents in \(M_h\), \(q(C)\) is a subset of the pre-two-faced submanifold \(A_1\), which is a contradiction. Therefore, we have either \(R = S\) or \(R \cap S = \emptyset\) for \(n\)-crescents \(R\) and \(S\) in \(M^t\). Finally, since the completion \(M_h^s\) of the holonomy cover \(M_h^s\) is a subset of \(M^t\), we also have \(R = S\) or \(R \cap S = \emptyset\) for \(n\)-crescents \(R\) and \(S\) in \(M_h^s\).

The above shows that \(M^s\) has no two-faced submanifold arising from hemispheric \(n\)-crescents. Let \(\mathcal{H}\) denote the set of all hemispheric \(n\)-crescents in \(M_h^s\). As in Chapter 9, \(p|_{\bigcup_{R \in \mathcal{H}} R \cap M_h^s}\) is a covering map to the finite disjoint union \(K\) of compact concave affine manifolds of type I. Since any two hemispheric \(n\)-crescents are equal or disjoint, it is easy to see that \(p^{-1}(K^o) = \bigcup_{R \in \mathcal{H}} R^o\). Then \(N, N = M^s - K^o,\) is a real projective \(n\)-manifold with totally geodesic boundary; in fact, \(M^t\) decomposes into \(N\) and \(K\) along totally geodesic \((n-1)\)-dimensional submanifold

\[
p(\bigcup_{R \in \mathcal{H}} \nu_R \cap M_h^s).
\]

We see that \(p^{-1}(N)\) equals \(M_h^s - p^{-1}(K^o)\), and so \(M_h^s - p^{-1}(K^o)\) covers \(N\). As we saw in Chapter 8, we may choose a component \(L_i^t\) of \(M_h^s - p^{-1}(K^o)\) for each component \(L_i\) of \(N\) covering \(L_i\) as a holonomy cover with the developing map \(\text{dev}|L_i^t\) and a holonomy homomorphism as described there; \(\coprod_{i=1}^{n} L_i^t\) becomes a holonomy cover \(N_h\) of \(N\) by Lemma 8.1.
We will show that $N_h$ includes no hemispheric $n$-crescent, which implies that $N$ includes no concave affine manifold of type I by the converse portion of Theorem 9.3. This completes the construction of the second column of arrows of equation 10.1.

The Kuiper completion of $L'_2$ is denoted by $L'_2$. The Kuiper completion $N_h$ of $N_h$ equals the disjoint union of $L'_2$. Since the inclusion map $i : L'_2 \to M_h^*$ is distance-decreasing, it extends to $i : N_h \to M_h^*$. If $N_h$ includes any hemispheric $n$-crescent $R$, then $i(R)$ is a hemispheric $n$-crescent by Proposition 8.3. Since $i(R) \cap M_h$ is a subset of $p^{-1}(K)$ by the construction of $K$, and $R^c \subset i(R) \cap M_h^*$, it follows that $R^c \subset p^{-1}(K)$. On the other hand, since $N_h \cap p^{-1}(K)$ equals $p^{-1}(\partial K)$, it follows that $N_h \cap p^{-1}(K)$ includes no open subset of $M_h^*$. Since $R^c \subset N_h$, this is a contradiction. Therefore, $N_h$ includes no hemispheric $n$-crescent.

We see after this stage that the completions of the covers of the subsequently constructed manifolds include no hemispheric $n$-crescents as the splitting and taking submanifolds do not affect this fact by Proposition 8.9.

Now we go to the second stage of the construction. Suppose that $N_h$ includes bihedral $n$-crescents and $A_2$ is the two-faced $(n-1)$-submanifold arising from bihedral $n$-crescents. Then we obtain the splitting $N^*_{h}$ of $N$ along $p(A_2)$.

We split $N_h$ along $A_2$ to obtain $N^*_{h}$. Then the holonomy cover $N^*_h$ of $N^*$ is a disjoint union of components of $N^*_{h}$ chosen for each component of $N^*$. Let $N^*_h$ denote the completion.

The reasoning using Proposition 8.10 as in the eighth paragraph above shows that $\Lambda(R) = \Lambda(S)$ or $\Lambda(R) \cap \Lambda(S) = \emptyset$ for every pair of bihedral $n$-crescents $R$ and $S$ in $N^*_h$. Theorem 9.3 shows that $N^*$ includes the finite disjoint union $T$ of concave affine manifolds of type II with the covering map

$$p \mid \bigcup_{R \in B} \Lambda(R) \cap N^*_h : \bigcup_{R \in B} \Lambda(R) \cap N^*_h \to T$$

where $B$ denotes the set of representatives of the equivalence classes of bihedral $n$-crescents in $N^*_h$. And we see that $N^* - T^*$ is a real projective manifold with convex boundary while $T$ has concave boundary. By letting $S = N^* - T^*$, we see that $N^*$ decomposes into $S$ and $T$.

Each component $J$ of $T$ is a maximal compact concave affine manifold of type II. If not, then $J$ is a proper submanifold of a compact concave affine manifold $J'$ of type II in $N^*$. A component of $p^{-1}(J)$ is a proper subset of a component of $p^{-1}(J')$. By Proposition 8.3, $p^{-1}(J')$ is a subset of $\bigcup_{R \in B} \Lambda(R) \cap N^*_h$. This is absurd.

For each component $S_i$ of $S$, we choose a component $S'_i$ of $N^*_h - p^{-1}(T^*)$. Then $\bigsqcup S'_i$ is a holonomy cover $S_h$ of $S$. The projective completion $\tilde{S}_h$ equals the disjoint union $\bigsqcup S'_i$. As in the sixth paragraph above, we can show that $\tilde{S}_h$ includes no bihedral $n$-crescent using Proposition 8.3. By the converse part of Theorem 9.3, we see that $\tilde{S}_h$ includes no compact concave affine manifold.

If $S$ is not $(n-1)$-convex, then $\tilde{S}_h$ includes an $n$-crescent since the proof of Theorem 4.6 easily generalizes to the case when the real projective manifold $M$ has convex boundary instead of totally geodesic one or empty one. Since $\tilde{S}_h$ does not include a hemispheric or bihedral $n$-crescent, it follows that $S$ is $(n-1)$-convex.
Now, we will show that the decomposition of Corollary 1.2 is canonical. First, the two-faced submanifolds \( A_1 \) and \( A_2 \) are canonically defined. Now let \( M = \mathcal{M}^n \) and \( N = N^s \) for convenience. First, suppose that \( M \) decomposes into \( N' \) and \( K' \) where \( K' \) is a submanifold whose components are compact concave affine manifolds of type I and \( N' \) is the closure of \( M - K' \) and \( N' \) includes no compact concave affine manifold of type I. We will show that \( N' = N \) and \( K' = K \).

Let \( K_i', i = 1, \ldots, n, \) be the components of \( K' \), \( K_{i,h}' \) their respective holonomy cover, and \( R_i' \) the projective completions, which equals a hemispheric \( n \)-crescent \( R_i \). We claim that \( p^{-1}(K'_i) \) equals \( \bigcup R \in \mathcal{H} R \cap M_h \), where \( \mathcal{H} \) is the set of all \( n \)-crescents in \( M_h \).

Each component \( K_{i,j}' \) of \( p^{-1}(K'_i) \) is a holonomy cover of \( K'_i \) (see Chapter 8). Let \( t_i' \) denote the lift of the covering map \( K_{i,h}' \rightarrow K_i' \) to \( K_{i,j}' \) which is a homeomorphism. We claim that \( p^{-1}(K'_i) \) equals \( \bigcup R \in \mathcal{H} R \cap M_h \) where \( \mathcal{H} \) is the set of all \( n \)-crescents in \( M_h \).

Suppose that there exists a hemispheric \( n \)-crescent \( R \) in \( M_h \) so that \( R \cap M_h \) is not a subset of \( p^{-1}(K') \). Suppose \( R \) meets \( p^{-1}(K') \). Then \( R \) meets a hemispheric \( n \)-crescent \( S \) where \( S \cap M_h \subset p^{-1}(K') \). If \( R \) and \( S \) overlap, then \( R = S \), which is absurd. Thus, \( R \cap M_h \) and \( S \cap M_h \) may meet only at \( \nu_R \cap M_h \) and \( \nu_S \cap M_h \). Hence, \( R \cap M_h \) in \( M_h \) is a subset of \( p^{-1}(M - K') \). Since each component of \( p^{-1}(M - K') \) is a holonomy cover of a component of \( M - K' \), it follows that the completion of a holonomy cover of a component of \( M - K' \) includes a hemispheric \( n \)-crescent by Proposition 8.3.

The part \( N' \) has no two-faced submanifold of type I since otherwise we easily see that such a submanifold becomes a two-faced submanifold of type I for \( M \) itself by Proposition 8.9. Since \( N' \) includes no compact concave affine manifold of type I, the converse part of Theorem 9.3 shows that \( N' \) includes no hemispheric \( n \)-crescent where \( N' \) is the completion of the holonomy cover \( N'_h \) of \( N' \). As this is a contradiction, we have that \( p^{-1}(K') \) equals \( \bigcup R \in \mathcal{H} R \cap M_h \). Therefore, we obtain \( N' = N \) and \( K' = K \).

Second, if \( N \) decomposes into \( S' \) and \( T' \) where \( T' \) is the finite union of a maximal compact concave affine manifold of type II, and \( S' \) includes no compact concave affine manifold of type II, then we claim that \( S' = S \) and \( T' = T \). As above, we show that \( p^{-1}(T') \) is a disjoint union of sets of form \( \Delta(R) \cap N_h \) for a bihedral crescent \( R \) in \( N_h \) using maximality. As above, the converse part of Theorem 9.3 shows that the completion of the holonomy cover of each component of \( S' \) does not include a set of from \( \Delta(R) \cap N_h \) for a bihedral \( n \)-crescent \( R \). The rest of proof is the same as in the hemispheric case. \( \square \)
Finally, we end with an application to affine Lie groups. Let $G$ be a Lie group with a left-invariant real projective structure, which means that $G$ has a real projective structure and the group of left-translations are projective automorphisms.

As $G$ is a manifold with real projective structure, there is an associated developing map $\tilde{G} \to \mathbb{S}^n$ and a holonomy homomorphism $\pi_1(G) \to \text{Aut}(\mathbb{S}^n)$. Let $G_h$ be the holonomy cover with induced development pair $(\text{dev}, h)$. Then $G_h$ is also a Lie group with the induced real projective structure, which is clearly left-invariant. Moreover, given an element $g$ of $G_h$, as $\text{dev} \circ L_g$ is another developing map for the left-translation $L_g$ by $g$, $\text{dev} \circ L_g = h'(g) \circ \text{dev}$ for an element $h'(g)$ of $\text{Aut}(\mathbb{S}^n)$. We see easily that $h' : G_h \to \text{Aut}(\mathbb{S}^n)$ is a homomorphism, which is still said to be a holonomy homomorphism.

As before if $G$ is not $(n-1)$-convex, then $G_h$ is not projectively diffeomorphic to an open $n$-bihedron or an open $n$-hemisphere.

**Theorem 11.1.** — If $G$ is not $(n-1)$-convex as a real projective manifold, then the projective completion $\tilde{G}_h$ of $G_h$ includes an $n$-crescent $B$.

**Proof.** — This is proved similarly to Theorem 4.6 by a pull-back argument. The reason is that the left-action of $G_h$ on $G_h$ is proper and hence given two compact sets $K$ and $K'$ of $G_h$, the set $\{ g \in G_h | \text{dev}(g(K)) \cap \text{dev}(K') \neq \emptyset \}$ is a compact subset of $G_h$. That is, all arguments of Chapter 4 go through by choosing an appropriate sequence $\{g_i\}$ of elements of $G_h$ instead of deck transformations. Obviously, if $G_h$ includes a cocompact discrete subgroup, then this is a corollary of Theorem 4.6. But if not, this parallel argument is needed.

Suppose that from now on $G_h$ includes an $n$-crescent $B$. Since the action of $G_h$ on $G_h$ is transitive, $G_h$ equals the union of $g(B)$ for $g \in G_h$. We claim that $g(B) \sim g'(B)$ for every pair of $g$ and $g'$ in $G_h$: That is, there exists a chain of $n$-crescents $B_i$, $i = 1, \ldots, k$, of same type as $B$ so that $B_1 = g(B)$, $B_i$ overlaps with $B_{i+1}$ for each $i = 1, \ldots, k-1$, and $B_k = g'(B)$: Let $x$ be a point of $B^o$ and $B(x)$ a tiny ball of $x$ in $B^o$. We can choose a sequence $g_0, \ldots, g_n$ with $g_0 = g$ and $g_n = g'$ where $g_{i+1}^{-1}g_i(x)$
belongs to $B(x)^o$. In other words, we require $g_i^{-1}g_i$ to be sufficiently close to the identity element. Then $g_i(B^o) \cap g_{i+1}(B^o) \neq \emptyset$ for each $i$. Hence $g(B) \sim g(B)$ for any pair $g, g' \in G_h$.

If $B$ is an $n$-hemisphere, then we claim that $g(B) = B$ for all $g$ and $G_h = B \cap G_h$. The proof of this fact is identical to that of Theorem 5.1 but we have to use the following lemma instead of Lemma 5.2.

**Lemma 11.2.** — Suppose that $\text{dev} : G_h \rightarrow S^n$ is an imbedding onto the union of two $n$-hemispheres $H_1$ and $H_2$ meeting each other on an $n$-bihedron or an $n$-hemisphere. Then $H_1 = H_2$, and $G_h$ is projectively diffeomorphic to an open $n$-hemisphere.

**Proof.** — If $H_1$ and $H_2$ are different, as in the proof of Lemma 5.2 we obtain two $(n-1)$-dimensional hemispheres $O_1$ and $O_2$ in $G_h$ where a subgroup of index one or two in $G_h$ acts on. Since the action of $G_h$ is transitive, this is clearly absurd. □

So if $B$ is an $n$-hemisphere, then we obtain $G_h = B \cap G_h$. Since $G_h$ is boundary-less, $\delta B$ must consist of ideal points, which contradicts the definition of $n$-crescents. Therefore, every $n$-crescent in $G_h$ is a bihedral $n$-crescent.

The above shows that $G_h \subset \Lambda(B)$ for a bihedral $n$-crescent $B$, $G_h$ is a concave affine manifold of type II and hence so is $G$. To prove this, we need to show that two overlapping $n$-crescents intersect transversally as the proof for the Lie group case is slightly different. The transversality is proved entirely as in the proof of Theorem 5.4 using Lemma 11.2 instead of Lemma 5.2.

Let $H$ be a Lie group acting transitively on a space $X$. It is well-known that for a Lie group $L$ with left-invariant $(H, X)$-structure, the developing map is a covering map onto its image, an open subset (see Proposition 2.2 in Kim [23]). Thus $\text{dev} : G_h \rightarrow S^n$ is a covering map onto its image.

Recall that $\text{dev}$ maps $\Lambda(B)^o$ into an open subset of an open hemisphere $H$, and $\delta \Lambda(B) \subset \Lambda(B)$ is mapped into the boundary $S^{n-1}$ of $H$. Each point of $G_h$ belongs to $S^o$ for an $n$-crescent $S$ equivalent to $R$ since the action of $G_h$ on $G_h$ is transitive (see above). Since each point of $\text{dev}(G_h)$ belongs to the interior of an $n$-bihedron $S$ with a side in $S^{n-1}$, the complement of $\text{dev}(G_h)$ is a closed convex subset of $H$. Thus, $\text{dev}|G_h$ is a covering map onto the complement of a convex closed subset of $\mathbb{R}^n$. As $\hat{G}$ covers $G_h$, we see that this completes the proof of Theorem 1.4.

An affine $m$-convexity for $1 \leq m < n$ is defined as follows: Let $M$ be an affine $n$-manifold, and $T$ an affine $(m + 1)$-simplex in $\mathbb{R}^n$ with sides $F_1, F_2, \ldots, F_{m+2}$. Then $M$ is affine $m$-convex if every nondegenerate affine map $f : T^o \cup F_2 \cup \cdots \cup F_{m+2} \rightarrow M$ extends to one $T \rightarrow M$ (see [16] for more details).

If $G$ has a left-invariant affine structure, then $G$ has a compatible left-invariant real projective structure. It is easy to see that the $(n-1)$-convexity of $G$ in the real projective sense is equivalent to the affine $(n-1)$-convexity of $G$.

By Theorem 1.4, $G$ is either $(n-1)$-convex or $G_h$ is a concave affine manifold of type II. As before, if $G_h$ is a concave affine manifold of type II, the argument above shows that $G_h$ is mapped by $\text{dev}$ to the complement of a closed convex set in $\mathbb{R}^n$. This completes the proof of Corollary 1.5.
Finally, we easily see that the following theorem holds with the same proof as the Lie group case:

**Theorem 11.3.** — Let $M$ be a homogeneous space on which a Lie group $G$ acts transitively and properly. Suppose $M$ has a $G$-invariant real projective structure. Then $M$ is either $(n-1)$-convex, or $M$ is concave affine of type II. Also, $M$ is affine $(n-1)$-convex or $M$ is concave affine of type II if $M$ has a $G$-invariant affine structure.
PART III

APPENDICES
APPENDIX A

TWO MISCELLANEOUS THEOREMS

We prove in this section the fact that 3-manifolds with homogeneous Riemannian geometric structures admit real projective structures, and Theorem 4.5 on the equivalent definitions of convex real projective manifolds. The proofs are a little sketchy here; however, they are elementary.

Recall that given a pair of a space \( X \) and a Lie group \( G \) acting on \( X \), Klein defined \((X, G)\)-geometry as the \( G \)-invariant properties on \( X \). An \((X, G)\)-structure on a manifold is given by a maximal atlas of charts to \( X \) with transition functions lying in \( G \).

Given the product space \( \mathbb{R}P^2 \times \mathbb{R}P^1 \), the group \( \text{PGL}(3, \mathbb{R}) \times \text{PGL}(2, \mathbb{R}) \) acts on the space in the standard manner; i.e., \((g, h)(x, y) = (g(x), h(y))\) for \( x \in \mathbb{R}P^2, y \in \mathbb{R}P^1, g \in \text{PGL}(3, \mathbb{R}) \), and \( h \in \text{PGL}(2, \mathbb{R}) \). The geometry modeled on the pair is said to be the product real projective geometry and the geometric structure modeled on the geometry is said to be the product real projective structure.

The following theorem is proved essentially using Molnár’s work [26]. (See also Thiel [32].)

**Theorem A.1.** — Let \( M \) be a 3-manifold with Riemannian homogeneous structure. Then \( M \) admits a real projective structure or a product real projective structure.

**Proof.** — The Euclidean, spherical, and hyperbolic geometries correspond to the pairs \((\mathbb{R}^n, O(n, \mathbb{R}) \cdot \mathbb{R}^n), (\mathbb{S}^n, O(n + 1, \mathbb{R}))\), and \((H^n, \text{PSO}(1, n))\). Here, \( O(n, \mathbb{R}) \) denotes the group of orthogonal transformations of \( \mathbb{R}^n \), and \( O(n, \mathbb{R}) \cdot \mathbb{R}^n \) the orthogonal group extended by translations, i.e., the group of rigid motions of \( \mathbb{R}^n \). \( H^n \) denotes the positive part of the conic in \( \mathbb{R}^{n+1} \) given by \( x_0^2 - x_1^2 - \cdots - x_n^2 = 1 \), and \( \text{PSO}(1, n) \) the group of linear transformations acting on \( H^n \).

As we said above, \( \mathbb{R}^n \) is an affine patch and the group of rigid motions are affine, and hence projective. \( H^n \) can be identified with an open ball in \( \mathbb{R}P^n \), with \( \text{PSO}(1, n) \) identified with an obvious copy in \( \text{PGL}(n + 1, \mathbb{R}) \). Hence, these geometries can be considered as a pair of open subsets in \( \mathbb{R}P^n \) or \( \mathbb{S}^n \) and subgroups of projective automorphisms of the open subsets respectively. Hence, an \((X, G)\)-atlas for each of
these geometries \((X,G)\) is a real projective atlas, and so the three-manifold with an 
\((X,G)\)-structure admits real projective structures.

Using the notation in Scott’s paper [29], the geometries \(\text{Sol}, \text{Nil},\) and \(\widetilde{SL}(2,\mathbb{R})\) 
can be realized as pairs of open subsets of real projective space \(\mathbb{R}P^3\) or real projective 
spheres \(S^3\) and subgroups of projective automorphism groups. This can be seen in 
Molnár [26] as he gives explicit domains and the group of projective automorphisms 
corresponding to the isometry group. Hence, 3-manifolds admitting these structures 
also admit real projective structures.

For \(H^2 \times \mathbb{R}^1\), and \(S^2 \times \mathbb{R}^1\) geometries, as two-dimensional hyperbolic and spherical 
geometries are realized by projective models, we see easily that they have models 
subsets of \(\mathbb{R}P^2 \times \mathbb{R}P^1\) with the automorphism groups subgroups of \(\text{PGL}(3,\mathbb{R}) \times \text{PGL}(2,\mathbb{R})\). \(\square\)

**Theorem A.2** — Let \(M\) be a real projective \(n\)-manifold. The following are equivalent:

1. \(M\) is 1-convex.
2. \(M\) is convex.
3. \(M\) is real projectively isomorphic to a quotient of a convex domain in \(\mathbb{S}^n\).

Furthermore, \(M_h\) can be identified with \(\tilde{M}\) if any of the above items is true.

**Proof.** — (1) \(\Rightarrow\) (2): Since \(M\) is 1-convex, \(\tilde{M}\) is 1-convex. Any two points \(x\) and \(y\) in \(\tilde{M}\) 
are connected by a chain of segments \(s_i, i = 1, \ldots, n\), of \(d\)-length \(< \pi\) with endpoints 
\(p_i\) and \(p_i^2\) so that \(s_i \cap s_{i+1} = \{p_{i+1}\}\) exactly. This follows since any path may be 
covered by tiny balls which are convex. We will show that \(x\) and \(y\) are connected by 
a segment of \(d\)-length \(\leq \pi\).

Assume that \(x\) and \(y\) are connected by such a chain with \(n\) being a minimum. We 
can assume further that \(s_i\) are in a general position, i.e., \(s_i\) and \(s_{i+1}\) do not extend 
each other as an imbedded geodesic for each \(i = 1, \ldots, n - 1\), which may be achieved 
by perturbing the points \(p_2, \ldots, p_n\), unless \(n = 2\) and \(s_1 \cup s_2\) form a segment of \(d\)-
length \(\pi\); in which case, we are done since \(s_1 \cup s_2\) is the segment we need. To show we 
can achieve this, we take a maximal sequence of segments which extend each other 
as geodesics. Suppose that \(s_i, s_{i+1}, \ldots, s_j\) form such a sequence for \(j > i\). Then the 
total length of the segment will be less than \(\pi[j - i]\). We divide the sequence into 
new segments of equal \(d\)-length \((< \pi)\) \(s_i', s_{i+1}', \ldots, s_j'\) where \(s_i'\) has new endpoints 
\(p_i', p_{i+1}'\) for \(i \leq k \leq j\) where \(p_i' = p_i\) and \(p_{j+1}' = p_{j+1}\). Then we may change \(p_k'\) 
for \(k = i + 1, \ldots, j\) toward one-side of the segments by a small amount generically. 
Since \(p_k'\), \(k = i + 1, \ldots, j\), are in an open hemisphere (an affine patch) determined by 
the original geodesic \(s_i \cup \cdots \cup s_j\), we see that new segments \(s_i'', s_{i+1}'', \ldots, s_j''\) are in 
general position together with \(s_{i-1}\) and \(s_{j+1}\). This would work unless \(j - i = 2\) and 
the total \(d\)-length equals \(\pi\) since in this case changing \(p_{i+1}'\) still preserves \(s_i'' \cup s_{i+1}''\) to be a segment of \(d\)-length \(\pi\). However, since \(n \geq 3\), we may move \(p_i'\) or \(p_{j+1}'\) in some 
direction to put the segments into a general position.
Let us choose a chain $s_i, i = 1, \ldots, n,$ of segments with minimal number of segments, in general position. We assume that we are not in case when $n = 2$ and $s_1 \cup s_2$ forming a segment of $d$-length $\pi$.

We show that the number of the segments equals one, which shows that $\tilde{M}$ is convex. If the number of the segments is not one, then we take $s_1$ and $s_2$ and parameterize each of them by projective maps $f_i : [0, 1] \to s_i, i = 1, 2,$ so that $f_i(0) = p_2$. Then since a tiny ball $B(p_2)$ can be identified with a convex ball in an affine patch, it follows that for $t$ sufficiently small there exists a nondegenerate real projective map $f_t : \Delta_t \to B(p_2)$ where $\Delta_t$ is a triangle in $\mathbb{R}^d$ with vertices $(0, 0), (t, 0),$ and $(0, t)$ and $f_t(0, 0) = p_2, f_t(s, 0) = f_1(s)$ and $f_t(0, s) = f_2(s)$ for $0 \leq s \leq t$.

We consider the subset $A$ of $(0, 1]$ so that $f_t : \Delta_t \to \tilde{M}$ is defined. For $t \in A$, $f_t : \Delta_t \to \tilde{M}$ is always an imbedding since $\text{dev} \circ f_t$ is a nondegenerate projective map $\Delta_t \subset S^n \to S^n$. Thus $A$ is open in $(0, 1]$ since as $f(t)$ is compact, there exists a convex neighborhood of it in $\tilde{M}$ where $\text{dev}$ restricts to an imbedding.

We claim that $A$ is closed by 1-convexity: we consider the union $K = \bigcup_{t \in A} f_t(\Delta_t)$. Then the closure of $K$ in $\tilde{M}$ is a compact triangle in $\tilde{M}$ with two sides in $s_1$ and $s_2$. Since two sides of $K$ and $K^c$ are in $\tilde{M}$, $K$ itself is in $\tilde{M}$ by 1-convexity. Hence $A$ must equal $(0, 1]$ and there exists a segment $s'_1$ of $d$-length $< \pi$, namely $f_1((0, 0)(0, 1))$, connecting $p_1$ and $p_3$. This contradicts the minimality, and $x$ and $y$ are connected by a segment of $d$-length $\leq \pi$.

$\text{(2)} \rightarrow \text{(3)}$ As $\tilde{M}$ is convex, the closure of $\tilde{M}$ in $\tilde{M}$ is tame as we explained in Chapter 3. Thus $\tilde{M}$ is a tame set, $\text{dev} : \tilde{M} \to S^n$ is an imbedding onto a convex subset of $S^n$, and $\text{dev}|\tilde{M}$ is an imbedding onto a convex subset of $S^n$. Since the equation $\text{dev} \circ \vartheta = h(\vartheta) \circ \text{dev}$ holds for each deck transformation $\vartheta$ of $\tilde{M}$, it follows that $\text{dev}$ induces a real projective diffeomorphism $\tilde{M}/\pi_1(M) \to \text{dev}(\tilde{M})/h(\pi_1(M))$.

$\text{(3)} \rightarrow \text{(1)}$ Since $\tilde{M}$ can be identified with a convex domain in $S^n$, $\tilde{M}$ is 1-convex from the definition of 1-convexity. \qed
APPENDIX B

SHRINKING AND EXPANDING $n$-BALLS BY PROJECTIVE MAPS

Proposition B.1. — Suppose we have a sequence of $e$-$d$-balls $B_i$ in a real projective sphere $S^n$ for some $n \geq 1$ and a fixed positive number $e$ and a sequence of projective maps $\varphi_i$. Assume the following:

- The sequence of $d$-diameters of $\varphi_i(B_i)$ goes to zero.
- $\varphi_i(B_i)$ converges to a point, say $p$, in the Hausdorff sense.
- For a compact $n$-ball neighborhood $L$ of $p$, $\varphi_i^{-1}(L)$ converges to a compact set $L_{\infty}$.

Then $L_{\infty}$ is an $n$-hemisphere.

Recall that $\mathbb{R}^{n+1}$ has a standard Euclidean metric and $d$ on $S^n$ is obtained from it by considering $S^n$ as the standard unit sphere in $\mathbb{R}^{n+1}$.

The Cartan decomposition of Lie groups states that a real reductive Lie group $G$ can be written as $KTK$ where $K$ is a compact Lie group and $T$ is a maximal real tori. Since $\text{Aut}(S^n)$ is isomorphic to $\text{SL}_+(n+1, \mathbb{R})$, we see that $\text{Aut}(S^n)$ can be written as $O(n+1)D(n+1)O(n+1)$ where $O(n+1)$ is the orthogonal group acting on $S^n$ as the group of isometries and $D(n+1)$ is the group of determinant $1$ diagonal matrices with positive entries listed in decreasing order where $D(n+1)$ acts in $S^n$ as a subgroup of $\text{GL}(n+1, \mathbb{R})$ acting in the standard manner on $S^n$. In other words, each element $g$ of $\text{Aut}(S^n)$ can be written as $i(g)d(g)i'(g)$ where $i(g)$ and $i'(g)$ are isometries and $d(g) \in D(n+1)$ (see Carrière [8] and Choi [16], and also [15]).

We may write $\varphi_i$ as $K_{1,i} \circ D_i \circ K_{2,i}$ where $K_{1,i}$ and $K_{2,i}$ are $d$-isometries of $S^n$ and $D_i$ is a projective map in $\text{Aut}(S^n)$ represented by a diagonal matrix of determinant $1$ with positive entries. More precisely, $D_i$ has $2n+2$ fixed points $[\pm e_0, \ldots, \pm e_n]$, the equivalence classes of standard basis vectors $\pm e_0, \ldots, \pm e_n$ of $\mathbb{R}^{n+1}$, and $D_i$ has a matrix diagonal with respect to this basis; the diagonal entries $\lambda_i$, $i = 0, 1, \ldots, n$, are positive and in decreasing order. Let $O_{[\pm e_0]}$ denote the open $n$-hemisphere containing $[\pm e_0]$ whose boundary is the great sphere $S^{n-1}$ containing $[\pm e_j]$ for all $j$, $j \geq 1$, and $O_{[-e_0]}$ that containing $[-e_0]$ with the same boundary set.

Since $\varphi_i(B_i)$ converges to $p$, and $K_{1,i}$ is an isometry, the sequence of the $d$-diameter of $D_i \circ K_{2,i}(B_i)$ goes to zero as $i \to \infty$. We may assume without loss of generality
that \( D_i(K_2, i(B_i)) \) converges to a set consisting of a point by choosing a subsequence if necessary. By the following lemma B.2, \( D_i(K_2, i(B_i)) \) converges to one of the attractors \([e_0]\) and \([-e_0]\). We may assume without loss of generality that \( D_i(K_2, i(B_i)) \) converges to \([e_0]\).

Since \( L \) is an \( n \)-dimensional ball neighborhood of \( p \), \( L \) includes a \( d \)-ball \( B_\delta(p) \) in \( S^n \) with center \( p \) with radius \( \delta \) for some positive constant \( \delta \). There exists a positive integer \( N \) so that for \( i > N \), we have

\[
\varphi_i(p_i) \subset B_{\delta / 2}(p)
\]

for the \( d \)-ball \( B_{\delta / 2}(p) \) of radius \( \delta / 2 \) in \( S^n \). Letting \( q_i = \varphi_i(p_i) \) for the \( d \)-center \( p_i \) of the ball \( B_i \), we see that \( B_{\delta / 2}(q_i) \) is a subset of \( L \) for \( i > N \).

Since \( K_{1,i}^{-1}(q_i) = D_i \circ K_{2,i}(p_i) \), the sequence \( K_{1,i}^{-1}(q_i) \) converges to \([e_0]\) by the second paragraph above. There exists an integer \( N_1 \), \( N_1 > N \), such that \( K_{1,i}^{-1}(q_i) \) is of \( d \)-distance less than \( \delta / 4 \) from \([e_0]\) for \( i > N_1 \). Since \( K_{1,i}^{-1} \) is a \( d \)-isometry, \( K_{1,i}^{-1}(B_{\delta / 4}(q_i)) \) includes the ball \( B_{\delta / 4}([e_0]) \) for \( i > N_1 \). Hence \( K_{1,i}^{-1}(L) \) includes \( B_{\delta / 4}([e_0]) \) for \( i > N_1 \).

Since \([e_0]\) is an attractor under the action of the sequence \( \{D_i\} \) by Lemma B.2, the images of \( B_{\delta / 4}([e_0]) \) under \( D_i^{-1} \) eventually include any compact subset of \( O([e_0]) \). Thus, \( D_i^{-1}(B_{\delta / 4}([e_0])) \) converges to \( \text{Cl}(O_1) \) in the Hausdorff metric, and up to a choice of a subsequence \( K_{2,i}^{-1} \circ D_i^{-1}(B_{\delta / 4}([e_0])) \) converges to an \( n \)-hemisphere. The equation

\[
\varphi_i^{-1}(L) = K_{2,i}^{-1} \circ D_i^{-1} \circ K_{1,i}^{-1}(L) \\
\supseteq K_{2,i}^{-1} \circ D_i^{-1}(B_{\delta / 4}([e_0]))
\]

shows that \( \varphi_i^{-1}(L) \) converges to an \( n \)-hemisphere.

The straightforward proof of the following lemma is left to the reader.

**Lemma B.2.** — Let \( K_i \) be a sequence of \( e \)-\( d \)-balls in \( S^n \) and \( d_i \) a sequence of automorphisms of \( S^n \) that are represented by diagonal matrices of determinant 1 with positive entries for the standard basis with the first entry \( \lambda_i \) the maximum. Suppose \( d_i(K_i) \) converges to the set consisting of a point \( y \). Then there exists an integer \( N \) so that for \( i > N \), the following statements hold:

1. \([e_0]\) and \([-e_0]\) are attracting fixed points of \( d_i \).
2. \( y \) equals \([e_0]\) or \([-e_0]\).
3. The eigenvalue \( \lambda_i \) of \( d_i \) corresponding to \( e_0 \) and \(-e_0 \) is strictly larger than the eigenvalues corresponding to \( \pm e_j \), \( j = 1, \ldots, n \).
4. \( \lambda_i / \lambda_i' \to +\infty \) for the maximum eigenvalue \( \lambda_i' \) of \( d_i \) corresponding to \( \pm e_j \), \( j = 1, \ldots, n \).
FREQUENTLY USED SYMBOLS

\( A^o \): the topological interior of a convex set \( A \) in \( \langle A \rangle \).
\( \langle A \rangle \): the unique minimal great sphere including a convex subset \( A \) of \( S^n \).
\( \alpha_R \): the union of all open \((n-1)\)-hemispheres in the intersection of \( \delta R \) with the ideal set if \( R \) is a hemispheric \( n \)-crescent, or the interior of a side of \( R \) in the ideal set if \( R \) is a bihedral \( n \)-crescent.
\( \partial A \): the topological boundary of the set \( A \) with respect to the obvious largest ambient space.
\( \text{Cl}(A) \): the topological closure of \( A \) in the obvious largest ambient space.
\( \text{int} A \): the topological interior of \( A \) in the obvious largest ambient space.
\( e_R \): the union of copied components of a hemispheric \( n \)-crescent \( R \).
\( \delta A \): the manifold boundary of a manifold \( A \).
\( \delta_\infty A(R) \): the union of \( \alpha_S \) for all bihedral \( n \)-crecents \( S \) equivalent to an \( n \)-crescent \( R \).
\( A(R) \): the union of all bihedral \( n \)-crecents equivalent to an \( n \)-crescent \( R \).
\( M^o \): the manifold interior of a manifold \( M \).
\( M \): the Kuiper completion of the universal cover of \( M \).
\( \tilde{M} \): the universal cover of a manifold \( M \).
\( M_h \): the holonomy cover of a real projective manifold \( M \).
\( \tilde{M}_h \): the Kuiper completion of a holonomy cover \( M_h \).
\( M_{h,\infty} \): the set of ideal points of the Kuiper completion of a holonomy cover \( M_h \).
\( \tilde{M}_{\infty} \): the set of ideal points of the Kuiper completion of a universal cover \( \tilde{M} \).
\( \nu_R \): the complement of \( \alpha_R \) in \( \delta R \) if \( R \) is a hemispheric \( n \)-crescent or the side of \( R \) not in the ideal set if \( R \) is a bihedral \( n \)-crescent.
\( \partial A \): the topological boundary of a convex subset \( A \) in \( \langle A \rangle \) if \( A \) is a subset of \( S^n \), or the subset of \( \text{Cl}(A) \) corresponding to \( \partial B \) for the image \( B \) of \( A \) under the developing map if \( A \) is a tame subset of a Kuiper completion.
\( \pi_1(M) \): the fundamental group of a manifold \( M \) or the deck transformation group.
\( \mathbb{R} \): the real number field.
\( \mathbb{R}P^n \): the \( n \)-dimensional real projective space.
